latter tries to make profits, while the former does not. The business concern keeps down its expenses in order to increase its income; the government keeps down its expenses in order to diminish its income. It would therefore seem that the accounting system of the business concern is not entirely suited to governmental needs. Indeed such system must be greatly modified or devised on a different basis when applied to the government. It must be designed not to show profits but to furnish the information required in maintaining a balanced relation between the income and the outgo of the government. Of course where undertakings of a business nature, such as utilities, are publicly owned and operated, it is often advisable to apply accounts of a commercial type, particularly when these undertakings are conducted on a self-supporting or profit making basis. But this is not true of the major departments of government; they are not self-sustaining and, besides, they are non-profit making.

The modern public accounting system comprehends a series of more or less related records which may be divided into general accounts and cost accounts, the latter being detailed accounts relating mainly to expenditures. The general accounts, which are largely of a summary character, are the means of exercising control over income and outgo; they also express the financial condition of the government. The cost accounts support the general accounts; they supply detailed information, principally with respect to operating expenditures, which is needed in conducting administrative work.

Cost accounting is a recent development which had its beginning in the rapid growth of industry starting about 1900. As applied to industry it has perhaps been developed more extensively in the United States than in any other country. But it is as yet not widely applied to governmental functions, being limited largely to public works activities, certain institutional services, and publicly owned and operated utilities. The present movement to improve the quality of public administration is, however, stimulating the wider application of cost accounting to governmental operations.

A detailed discussion of the actual forms and the day-to-day procedure of keeping public accounts is beyond the scope of this treatment. Suffice it to say that these are matters which are largely determined by the financial requirements of the government and the information that is to be produced. Modern devices and

appliances are now being used in connection with the accounting systems of many governments. For example, loose leaf and card ledgers have largely displaced the old bound ledgers; the former are more satisfactory and effect a material saving in time. Ledger postings are now performed mechanically, the account being posted, the items added up, and a balance struck by one operation. The number of operations in recording and handling financial transactions has also been greatly reduced. In the billing of taxes, for instance, sufficient copies of the original bill are made by a single operation on a machine to cover each successive step in the procedure of payment, thus saving time and reducing the possibilities of error. Tabulating machines are now regarded as being indispensable to the accurate and speedy production of cost data or any detailed accounting analyses, such as the distribution of expenditures by objects.

In common practise public accounts are usually kept on the cash basis, that is, they merely record the moneys actually received and disbursed by the government. They furnish information only with respect to settlement and liquidation; they supply no data concerning revenues and receipts due the government or expenditure obligations incurred by the government. The latter data are necessary to the exercise of real budgetary control. Such data, as well as the information regarding settlement and liquidation, are produced by accounts kept on the accrual basis. When the accrual basis is used, the accounts indicate just where the government stands at any time during the fiscal year in the realization of its income as authorized by the adopted budget; they also show the free and unencumbered balance of every appropriation.

The accrual basis of accounting has not yet been widely adopted in government, although it is almost universally used by business and industry. The English and French accounting systems are still on the cash basis. In the United States the accounting systems of the national government and of the majority of state and local governments are also run on the cash basis, although authorities on public finance have long recommended the adoption of the accrual basis. Accounting systems on the accrual basis have recently been installed in a few state governments and in several city governments.

There is no direct supervision on the part of

the national government of the United States over the accounting systems of the state or local governments. However, several states supervise the accounts kept by local governments within their respective jurisdictions. This supervision relates mainly to the form of the accounts and to the procedure followed in rendering financial reports, the purpose being to bring about some uniformity. Frequently it extends to an audit of the local accounts by an officer or agent of the state government.

From a structural standpoint a necessary feature of any government is the centralization of its accounts, particularly the general accounts, in a single office. This has been the recent trend of development in American cities, especially those with the centralized mayor or the manager forms of government. Today the most advanced type of organization for keeping the general accounts consists of an office under the control of the executive, which is usually a bureau or division in a larger department of finance. This office is headed by a chief accounting officer with the title of controller, since no moneys are paid into or out of the treasury without his approval. He is responsible for supervising the entire accounting system of the government and for supplying the executive and his budget officer with the information required in financial management. There is also an independent audit of the books kept by the controller, which is usually conducted by an officer or agent responsible to the legislative body.

This type of financial organization with respect to the accounting work has not as yet been widely adopted by the state governments of the United States, Massachusetts and Virginia being the only states that have so far accepted the scheme practically without modification. The national government is now in the process of devising a central accounting system. When completed it will no doubt be installed in the General Accounting Office under the direction of the comptroller general, an agent of Congress. The president and his budget officer will then have to depend largely upon an office over which they have no control for the general information needed in executing the budget. Furthermore the comptroller general will in effect be the auditor of his own accounts. This arrangement, it appears, will lack some of the safeguards and much of the effectiveness of the British system. In England the accounts are under the supervision of the treasury, which is

the great executive department of finance, and the comptroller and auditor general, an agent of Parliament, performs the independent audit of these accounts and reports his findings to Parliament.

ACCUMULATION is, literally, a heaping up of good things; generally, a gathering together of valuables, as of cattle into herds, goods into stocks, lands into holdings, or securities into estates; and, technically, a setting aside of current resources to serve future purposes. In this stricter sense it is a process in both individual and social economy. The individual accumulates against a future contingency, such as unemployment, the education of children, dependency in old age; or he builds up an investment from which he expects an income. The community, through the acts of its several

members, stores up "capital," or "resources devoted to further production." The forms, the processes and the ends of accumulation respond to the changing circumstances of society.

In pre-industrial communities the ways of accumulation present great variety. The group, or the individual, makes provision against a future emergency by conserving the fruits of a harvest to last until the next one; by hoarding the overflow of fat years to overcome the dearth of lean ones; by commuting perishable commodities into hides, tobacco, trinkets or other durable goods in which values can be stored until the purchasing power is wanted. The individual makes sure of a future living by establishing himself in a trade, buying an office, acquiring a privilege, building up a landed estate, or lending out moneys at usury. An organized society attempts to make less precarious its future by increasing its flocks or boats or tools, building a dam against a turbulent river, dispossessing a neighboring tribe of fertile lands, increasing its store of ceremonial objects, or maintaining sorcerers to propitiate the gods of fertility.

Under different methods of organizing the economic community, the ways of increasing productive wealth present a like variety. In a feudal society an exaction of customary dues produces manor houses, enriched estates and churches. In a craft system, where simple trades are skilfully practised, the spare time of workers is converted into the needed increment of tools. In a self-sufficient agricultural economy a distribution of tasks between seasons provides a time for the making of fences, the erection of barns, and the creation of other "improvements." In a communal regime, where all labor may be conscripted, a group is released from other activities and appointed to the construction of "mighty works." Always, everywhere, the ways of personal and social accumulation are rooted in trade practise, traditional lore, accepted custom and social organization.

In contemporary society accumulation takes its character from the structure of industry. The larger process breaks apart into the more or less distinctive activities of saving, investment, the equipping of industries, and capitalization. In saving, the active agents are the individual, the corporation and the state. The individual as of old may lay by goods or hoard coins; but his surplus is usually a sum of money to be put to productive use. The corporation sets aside a part of its earnings to be used in its business

The state allocates a portion of its revenues to "public improvements." An enlargement of the province of government and an expansion of business have increased the demand for providence on the part of the state and the corporation; their current contribution to the volume of savings is estimated to be well above one third of the whole.

In the process of accumulation these savings are transmuted into the equipment of industries, or "capital goods," through investment. The conversion may be direct. An individual puts his money back into his business by increasing his stock or enlarging his shop. A corporation uses its surplus to improve its plant or to better its facilities. A state expends money in digging canals, erecting school houses and public buildings, and in making roads. Or the conversion may be effected indirectly through the agency of "the capital market." The investment broker, who is a middleman in handling accumulations, undertakes for a price to find productive uses for savings and savings for productive uses. Since many streams of savings must be coordinated with the needs of many businesses for funds, the activities which make up investment demand organization. Accordingly there has arisen a vast and intricate mechanism of stock exchanges, security markets and investment houses. It is through the mediation of this interlocking network of financial institutions that such accumulations as go to market are converted into the equipment of developing industries.

The practical test of the value of accumulations comes in the wake of investment. The value of the public works of the state is usually not set down in pecuniary terms; they are held of little or great account according as they are used and are appreciated. The accumulations of voluntary associations, in the form of churches, universities and hospitals, are appraised by those who control them in terms of the social ends they serve. But where industry is under business control, the market is called upon to evaluate the accumulations of individuals and of corporations. This ever continuous process is called capitalization. Accumulation has its beginning in the expectation of creating a valuable property; in the end this expectation may or may not be realized. If it is, the value is kept intact, and it may even appreciate. If it is not, the original saving is not easily to be withdrawn from the rather rigid stores, machinery, buildings and good will in which it is invested,

and depreciates. As a result of this constant revaluation capitalized accumulations may have very different values from those they possess as savings. Yet it is the capitalized value which determines how well the end which prompted saving has been realized.

In the literature of the subject the urge to accumulation has most often been set down as "the effective desire of the individual to save." A prudent man distributes his income over a period of time in such a way as best to serve his needs. A bit of uncertainty ahead quickens the incentive to save; an assurance of adequate future income invites more generous spending. The urge is strong in the forward looking individual and weak in the prodigal. It is stimulated by a rise in the rate of interest and retarded by a decrease in the reward of thrift. The volume of accumulations emerges as the result of countless individual judgments in each of which the utility of saving is nicely balanced against its cost.

In current writings accumulation is increasingly charged to the account of social conditions. Its foremost compulsion has come to be the opportunity which modern industry affords for the use of savings. So long as a rural economy and a petty trade prevailed, the demand for industrial equipment was small. The individual laid by against his own necessity; he accumulated wealth that he might give again to relieve distress or exact an uncanonical increment from persons in need. But with the coming of industrialism there has arisen a great demand for funds with which to launch enterprises, build up businesses, and create markets. It has been ingeniously contrived, by those who must have capital, to tempt the most unlike individuals to bring to the investment-market generous shares of their incomes. The timid have been baited with stocks and bonds which have combined safety of investment with small returns; the adventurous, with uncertain securities, a few of which bring to their holders rich prizes and the rest little or nothing. The active person has felt the lure to go adventuring with his own funds; the passive one has had his chance at gain through vicarious enterprising. An ingenious device called insurance has combined provision for an emergency with the creation of an estate. A market for savings, with its aggressive salesmanship and list of offerings accommodated to every variety of mind and temperament, has been brought to everyman's door.

A corresponding change in social values has stimulated the urge to accumulation. In the earlier days of Christendom the getting together of possessions was frowned upon as self-seeking. The words of the Gospels had put it beyond doubt that the soul's salvation demanded abstinence from worldly goods. "Lay not up for yourself treasures upon earth" had been thundered from the pulpit and enforced in the penitential, and doctors in theology had not yet interpreted away the plain import of the words. The addition of the command to "industry" brought the beginning of the change. In time a developing technology and increased national resources caused personal industry to be rewarded by handsome returns; the injunction to frugal living kept expenditures down; and the emerging surplus was the church's unwitting contribution to accumulation. Little by little "thrift" was elevated to the dignity of a cardinal virtue in what has been called "a holy economy"; and Puritanism became a powerful instrument in the formation of capital. Eventually its reward came to be possessed of a like value with thrift itself, the possession of vendible assets came to be a badge of honor, and only gains from the most unsavory sources were cursed as "tainted wealth." The resulting prestige which attaches to having and holding is today a great incentive toward accumulation.

It follows that the urge upon the individual to lay by varies with circumstances. An increase in income, a ready opportunity for gain, an assurance of security, an exposure to the homily of thrift, a worship of possessions promote accumulation. A decline in earnings, an ignorance of tempting opportunities, a fear of risking hard earned savings, a way of life that disposes one to take each day as it comes, an absorption in activities to which the market gives little support retard accumulation. A lag of habits of life behind a rising income makes savings almost inevitable; a lag of income behind an established way of life renders them well nigh impossible. In competitive accumulation the newcomer, who does not have to keep up appearances, has one decided advantage over the native with an established position to maintain. The upgrade of the business cycle encourages saving, the downgrade retards it; the maintenance of industry toward full capacity, even though it invites freer spending, promotes accumulation. In a society at any time, in respect to the effectiveness of the urge, the population may be divided into a number of

"thrift classes." To the captain of industry accumulation is inseparable from everyday activity; to the recipient of funded income it may be costless; to the professional man it may exact a toll in a loss of opportunity for personal attainment; to the unskilled worker it may mean a deprivation which is intolerable. But neither the classes nor the volume of savings is fixed; a statifying society is more likely to save than one which is statified; a period of transition is more favorable to accumulation than one of stability.

In like manner the savings of the corporation and of the state are rooted in opportunity, in value and in circumstance. The corporation cannot set aside a surplus unless its earnings permit, its directorate is sensitive to forward planning, and the business invites reinvestment. Earnings are of course not to go into improvements and betterments unless an adequate return is expected. But the matter presents no simple choice of the larger value; for, no matter how great may be the promised rewards, rarely are investments made outside the direct line of business. Moreover the discretion of those who decide is hemmed in by definite obligations to various classes of stockholders. Often reinvestment is due to sheer necessity; for, if funds can be found for expansion, there is opportunity for bigger things, while if they cannot, the corporation is likely to lose its business to a more enterprising competitor. Frequently a small group, who direct a capital many times their own holdings, have a chance to expand the business without the hazard of a loss of control which attends the sale of new securities. Always the creation of a surplus for reinvestment is an aspect of the policy of the corporation inseparable from its general aims and activities. The accumulations of the state are designed to meet clearly recognized needs of the population; they are rooted in considerations of public policy and are designed to serve ends which cannot be set down in pecuniary terms.

In the continuous and complex process of accumulation it is usual to find a social function. It is the way through which society "secures its capital," or "produced wealth is dedicated to future production." The discovery comes easily to those who see a single articulate process through which savings are without waste and with dispatch commuted into "capital goods." It comes with difficulty to those who regard saving, investment, the equipping of industry, and capitalization as loosely connected activ-

ities. It seems clear that the larger purpose is to be found within the myriad of individual, corporate and governmental doings; but the lesser activities do not serve the larger end with an undivided allegiance. Not all savings become investments. If there is a laying by for a future emergency there is a withdrawal to meet a present one. If personal income minus spendings equals savings, often personal income plus savings equals spending. In insurance it is the permanent fund, into which premiums go and out of which claims are paid, that goes to the capital market. In any period the increment in investments is to be found by subtracting withdrawals from savings. Nor are investments converted into a mass of industrial equipment of exactly the same value. In the capital market the broker takes his toll of the funds he handles, since even investment bankers must have a living wage. The use of commercial credit for investment purposes, the ratio of bank loans to deposits, the custom of paying for "financial services" in securities of a new corporation, the many usages which make of the capital market a distinctive institution, interpose between the number of dollars saved and the number which represents the value of the resulting "wealth devoted to further production." Nor do the initial values of consummated investments necessarily abide. There may be losses through the fallibility of human judgments, through a physical decay of goods whose values are not preserved through a charge for depreciation, through changes in technology which rob plant and equipment of their effective capacity to produce, or through a changed demand that will have none of the product. Thus between the initial savings of its members and a "permanent fund of social capital" there lies a network of institutions each of which has its wastes and its hazards. The current arrangements are a passing rather than a definitive provision for supplying the material equipment of the industrial system at a minimum of social cost.

The process of accumulation has often been called "social provision for the future." In the early days of industrialism, when it seemed that everything was possible if only funds were to be had, the term was not inexact. It is at least a question how much of a mass of capitalized values which primarily serves the gainful ends of individuals and corporations can be called social provision. Besides, there are other ways in which the community attempts to make the

future more secure: by the promotion of knowledge, the encouragement of technology, the advance of the industrial arts; by the establishment of customs and habits, such as the shorter working day and the constructive use of leisure, which tend to enrich human life; by the discovery, development and conservation of human resources; by making economic organization a better instrument for ordering the material means of living to serve its ends. The "investment" of savings in the improvement of institutions which may be passed on from generation to generation is an ancient and established way of providing for the future. At this point accumulation loses its identity in the larger process of enriching a developing cultural heritage.

A., *Work and Wealth* (New York 1914) p. 89-105; Johnson, Alvin S., "Influences Affecting the Development of Thrift" in *Political Science Quarterly*, vol. xxii (1907) 224-44; Friday, D., articles in *New Republic*, vol. xxix (1921-22) 64-67, vol. xxxiii (1922-23) 270-73, vol. xxxvii (1923-24) 304-05 and vol. xlii (1925) 65-67.

ACCURSIUS (1185-1263), jurist, born in Florence, a pupil of Azo at Bologna and professor there of Roman law. Accursius' great work is the *Glossa (ordinaria)* on the whole *Corpus Iuris*, finally summing up the results of the Bolognese school of Glossators. In courts following Roman law it virtually superseded the text (*Quidquid non agnoscit glossa nec agnoscit curia*) nor was it displaced there when dethroned in the schools by the humanists. It is immensely important not only for this reason but also because it is the great storehouse of information as to the Glossators, information which is still valuable for the interpretation of Roman law. Opinions vary greatly concerning its intrinsic merits; the best view rates them high. This work of Accursius is easily accessible in all early editions of the *Corpus Iuris*, but its serious use requires technical knowledge.

F. DE ZULUETA

ACHELIS, THOMAS (1850–1909), German sociologist and anthropologist. He studied philosophy and philology at Göttingen and from 1874 taught at the gymnasium in Bremen. From 1898 he edited the *Archiv für Religionswissenschaft*. His studies in anthropology reveal a certain philosophical-psychological trend which formed a contrast to the materialistic-physiological emphasis prevailing in Germany at that time; for that reason he was attacked by the Berlin school. Except for the short essay, *Rechtse Entstehung und Rechtsgeschichte* (Sozialer Fortschritt, no. 17, Leipsic 1904), the *Soziologie* (in Sammlung Göschen, 1st ed. Leipsic 1899, 2nd ed. 1912) is his most important work in the field of social science. Because it stands somewhat in opposition to the Hegelianism still dominant in German sociology, this treatise had less influence than it deserved considering the time of its appearance. According to Achelis, sociology is a study of the forms of human association, taking as its starting point man in his biological aspects and proceeding to a psychological explanation of associations. Above all, sociology must establish in basic outlines the structures of various social formations and, where possible, try to discover the underlying laws of relationship or at least the periodically recurring rhythms. For the most part, he would therefore proceed more inductively than had been done before him in Germany. However, he is by no means extreme; indeed, in concluding his chapter on principles and methods, he demands as supplementary the consideration of “teleological necessities,” because in social life motives and purposes constitute a residue not to be explained by the principle of mechanical causality.

R. THURNWALD

Important works: *Die Entwicklung der modernen Ethnologie* (Berlin 1889); *Die Entwicklung der Ehe* (Berlin 1893); *Mythologie und Kultus von Hawaii* (Brunswick 1895); *Moderne Völkerkunde* (Stuttgart 1896); *Ethik* (2nd ed. Leipsic 1900); *Die Wandlungen der Pädagogik im 19. Jahrhundert* (Berlin 1901); *Die Extase in ihrer kulturellen Bedeutung* (Berlin 1902); *Abriss der vergleichenden Religionswissenschaft* (Leipsic 1904); and the works mentioned in the text.

ACHENWALL, GOTTFRIED (1719–72), German statistician and student of public law. He studied first at Jena, where Smeitzel awakened in him a lasting interest in comparative politics and economics; then at Halle; and finally took his degree at Leipsic. After three years as tutor at Dresden he became

Privatdocent in history, statistics and the law of nature and of nations at Marburg in 1746. Upon his call to Göttingen, two years later, he wrote his first notable essay, “Vorbereitung zur Staatswissenschaft der europäischen Reiche” (1748). This became the introduction of his influential *Staatsverfassung der heutigen vornehmsten europäischen Reiche und Völker im Grundrisse* (Göttingen 1749; 6th ed. edited by his famous pupil August L. von Schlözer, Göttingen 1781; 7th ed. edited by M. C. Sprengel, Göttingen 1790–98). This used, for the first time, the term *Statistik*; it was translated into many languages and was widely imitated. It won for Achenwall the title, “father of statistics.” Nevertheless his work rested on that of Conring; and the school of political arithmetic, though quite different in method, preceded him.

By statistics Achenwall meant an inclusive description, comparative when possible, of the territory, population, industries, trade, social classes and political institutions of states. Its object was to enable statesmen to formulate policies of internal development and external relations in the light of definite knowledge. The “Achenwall school” relied mainly on verbal statement, and hence lost prestige with the accumulation of census and other numerical data. They made no contribution to what is now called statistical method.

FRANK H. HANKINS

Important works: *Naturrecht* (with J. S. Pütter, Göttingen 1750); *Grundsätze der europäischen Geschichte* (Göttingen 1754); *Jus naturae*, 2 vols. (Göttingen 1755–56); *Entwurf der allgemeineren europäischen Staatshandel*, a small work on European trade (Göttingen 1756); *Staatsklugheit nach ihren ersten Grundsätzen* (Göttingen 1761); *Juris gentium europæarum* (Göttingen 1775).

Falkner in *American Academy of Political and Social Science, Annals*, vol. i (1891) supplement; Achilles, Georg, *Die Bedeutung und Stellung von Gottfried Achenwall in der Nationalökonomie und Statistik* (Bern 1906); Schiefer, Paul, *Achenwall und seine Schule. Ihre Bedeutung für die heutige Entwicklung der Statistik* (Munich 1916).

ACKERSDIJCK, JAN (1790–1861), Dutch economist and statistician. From 1831 to 1860 he held a professorship in the faculty of law at Utrecht, lecturing on statistics, economics and history. He was a disciple of Adam Smith and spread free trade doctrines in Holland. Dutch

tariffs were modified in accordance with his views in 1845. He also effected a reminting of the coinage and pointed out ways of improving the state finances. In his travels he obtained an extensive knowledge of economic conditions in various countries and became greatly interested in statistics. As chairman of the government committee on statistics, organized on his initiative in 1858, and in other capacities he furthered the development of Dutch statistics, urging the publication of all data of importance from the social-economic point of view and the centralization of the various public statistical services.

F. PH. BICHON VAN IJSSELMONDE

Important works: *Bedenkingen over de Korencetten* (Objections to the Corn Laws) (Utrecht 1835); *Nederlands financiën*, 2 vols. (Amsterdam 1843); *Nederlands Muntwezen* (Utrecht 1845); *Over belastingen en bezuinigingen* (On Taxes and Savings) (Utrecht 1849); "Mouvement des idées économiques . . . en Hollande" in *Journal des économistes*, ser. ii, vol. xxviii (1860) 501-09.

ACLAND, JOHN (1699-1796), an early poor law reformer, born at Woodley, Beaford, Devon, and vicar of Broadclyst in that county from 1753 to the year of his death. His familiarity with the conditions of the poor and his conviction that the existing Poor Law encouraged poverty led him to publish in 1786 a pamphlet in which he expounded "A plan for rendering the poor independent on public contributions, founded on the basis of Friendly Societies, commonly called Clubs" (Exeter 1786). The plan was the establishment by statute of a central and national society which should make provision for the support of the dependent poor in sickness, unemployment and old age; marriage and maternity bounties were also to be provided. All adult workers of both sexes were to be required to contribute and the state was to make supplementary grants. A bill to this effect was introduced in the House of Commons but received little support. The scheme anticipated in every broad detail Mr. Lloyd George's great National Insurance Act of 1911.

W. H. DAWSON

Consult: Eden, F. M., *The State of the Poor*, 3 vols. (London 1797) vol. i, p. 373, 380.

ACOLLAS, EMILE (1826-91), French politician and jurist. He earned his living in Paris as a liberal professor of law, was an active member of the republican opposition to Napoleon III and was imprisoned in 1867. In

1870 he became professor of French law at the University of Bern, where in 1871 he proclaimed his sympathy with the Paris Commune. In 1876 he was a radical-socialist candidate for the Chamber of Deputies. He was not elected even though Garibaldi endorsed his candidacy in a eulogistic letter. In 1880 he accepted the office of inspector general of prisons from the French government and thenceforward renounced politics.

The idea that democracy must be realized in laws inspired his numerous juristic works. France was to undertake a complete revision of the Napoleonic codes. Laws pertaining to the family should protect the rights of women and children; property laws were to recognize labor as the single source of property rights; laws relating to municipal government were substantially to reduce the powers of the central government. For the true goal of democracy is individual independence. Acollas opposed the principle of popular sovereignty; he preferred individualistic to authoritarian democracy.

GEORGES WEILL

ACQUIRED CHARACTERS. *See* HEREDITY.

ACQUISITION is the word within whose confines is to be found the issue between private gain and public good. In every society an attempt is made to subdue personal advantage to the service of general welfare. A tribal commune sacrifices individual good to the necessities of the people; a feudal order invokes use and wont to restrict avarice to its due; a capitalistic society employs authority to keep business out of predatory activities. It is, however, only with the separation of the individual from the social economy, and with the distinction of the making of money from the production of a living, that the terms private gain and public good appear in clear cut relief. Accordingly the rise of commerce brings the question of the role of acquisition in social organization.

In the Middle Ages an antithesis was set up between private gain and public good. A feudal structure of society, in which each person held the station in life to which God had appointed

him, had little place for profits as a bait to get things done. The trafficking for gain lay upon fringes of a customary industrial system; its unworthy practitioners were beyond the pale of social respectability. It was taught that, since the value of an object was inherent within it, the trader could claim his ungodly reward only by buying at less or selling at more than worth. It was the duty of the Christian, as he would save his immortal soul, to keep himself "unspotted" from "the world" and his heart free from "covetous desire." He was permitted, eventually even encouraged, to provide goods against his own and his neighbor's necessities; but, since money was the root of all evil, the narrow path to heaven's gate was not by the way of affluence. The practise of the acquisitive arts was not unknown within the established system of fief, manor and church; but the structure of society, the judgment of respectability, the dialectic about value, and the Divine Word left to the calling of money making a scant and despicable place in the arrangements of man.

In the wake of industrialism acquisition came into an increased importance and an enhanced repute. The passing of otherworldliness endowed human nature with insatiable wants to be satisfied with material goods; the decline of feudalism and the decay of authority gave greater scope to the individual and invited a less stereotyped social order; the division of labor and the multiplication of goods made inevitable a market for their exchange and a pecuniary calculus for the measurement of their values. To the individual, profit or loss came to be "the beacon" which invited an increase or compelled decrease in production. A growth or decline in personal income, success or failure in business, was a blessing or a curse that came by way of the market. Thus acquisition came to connect individual productive effort with the maintenance of "the great industry."

In time popular thought made its customary accommodation to the changed role of money making in social organization. A trade, bad in itself or if pursued for gain, was to be allowed if its goods were used to relieve necessity. The danger to the public was not very imminent; a man knew what he wanted; the buyer was protected by the keenness of the rivalry between traders. Nor was it easy to fix the limits of tolerance; however harmful luxuries might be, their production made employment for persons who might otherwise become public charges.

Besides, the rich man could eat and wear little more than another; his surplus wealth he must invest in productive industry. In short, as Alice in Wonderland put it, it is "each person minding his own business" that "makes the world go round." In time ends and checks dropped out of the picture, and acquisition came to be of value in itself. A man has "a right" to "pursue an honest calling in an upright way" and to "do what he will with his own." The taboo upon avarice gave way to tolerance, and tolerance to rightful acceptance; thus was one of the seven deadly sins transformed into a cardinal virtue.

The philosophers converted this crude justification of acquisition into an articulate system. Its basis was the discovery of an inevitable connection between the expression of an individual instinct and the fulfilment of a social purpose. Cicero was quoted: "Bees do not congregate for the construction of the honeycomb; but, being by nature gregarious animals, combine their labor in the comb." Blackstone discovered as a foundation for law that "the Creator . . . has been pleased so to contrive the constitution and frame of humanity that we should want no other prompter to enquire after . . . but only our self-love, that universal principle of action." The deists translated "the Creator" into "Nature" and won for "the inseparable connection of justice with the happiness of each person" the status of immutable law. Hume came upon the great truth that the individual in seeking his true and substantial good promotes the larger purpose without being aware of what he is about. Adam Smith held that while the trader, "by directing . . . industry in such a manner as its produce may be of the greatest value . . . intends only his own gain, he is in this, as in many other cases, led by an invisible hand to promote an end which was no part of his intention," and condemned merchants "who affected to trade for the public good." With this lead the scholars translated "self-love" into "profit-seeking," created an "economic man" motivated by a "felicity calculus," made of the laws of supply and demand "economic harmonies," and obtained from the limited resources of society "the economic maximum" of foods. Acquisition thus became "the driving force" of an automatic, self-regulating and beneficent industrial order.

A repute so high was not to be retained even in a capitalistic society. The dominance of self-

interest as a motive and the pecuniary form of its expression have alike been challenged. The love of gain is only one of the incentives to action; it must take its chances along with the thirst for fame, the demand for the regard of one's fellows, the motive of service, idle curiosity and the urge toward self-expression. The pecuniary incentive varies from group to group; its hold is greater upon the promoter than upon the manufacturer, the merchant than the physician, the adventurer than the established man of business. Its compulsion is not uniform even upon members of a trade; there are degrees of mercy even among money lenders. The lure is not in gain, but in the unlike and incommensurable things money will buy; vendible things must compete with pleasures that money cannot purchase. Ofttimes activity has its source not in a demand for money but in the zest for a game in which money is the symbol and the token of success: "the man who plays cards for cowries is not mastered by a desire for cowries." Man is not "a lightning calculator of pleasures and pains who oscillates like a homogeneous globule of desire under the influence of 'pecuniary' stimuli." Activity is an expression of a working scheme of habits; acquisition is compelling or not as it is embodied in the customary ways of everyday life. These various lines of criticism, without denying to acquisition a power over the activities of men, take away its exclusiveness as an incentive, hedge it about with limits, and make it inadequate as a key to the organization of industry.

A challenge has likewise been leveled at the capacity of acquisition to direct industrial activity. The elemental urge of self-interest is aimless and untamed; it may be impelled in many directions, but can impel itself in none. It is the institutional system within which it is spent that gives its character and imparts form to its results. The Arabian sheik preying upon his neighbors, the monk parading his humility, the general seeking glory, the merchant counting up his gains, the social worker doing good, may all be personally acquisitive; yet acquisition does not explain their respective activities. The slave owner and the industrial employer may have a like devotion to personal gain; yet it is not acquisition, but the legal status of the laborer which impels the former to conserve his investment in human chattels and the latter to exact as much wear and tear as he can for the daily wage. It is not a smaller regard for profits, but a larger appreciation of long-time

values, which makes the corporation of today more considerate of laborers and customers, and more concerned with long-time planning, than it was a generation ago. If currently acquisition leads to the production of goods for sale, rather than to the robbery of neighbors or the laying up of treasures in heaven, it may be because of the compulsion which lurks in the prevailing order of society. If today money making is the dominant activity, it is not of necessity because man is actuated by pecuniary motives; it may well be because the conventions of society as now organized impel his activities toward pecuniary ends. Always and everywhere values, institutions and arrangements such as these compromise the acquisitive motive, confine it within channels, and direct it toward objectives. Its character, its uses, its effects are what they are because of the rules of the game under which we acquire.

Nor has criticism stopped with limiting acquisition to this more modest role in social organization. The neo-canonists, standing in the direct line of ecclesiastical tradition, adapt the older condemnation of avaricious individuals to the newer commercial economy. They discover a subordination of great industries to the ends of private gain, a welter of unearned incomes rooted in privilege and property, and a failure of society consciously to provide for the larger needs of its members. They denounce modern industrialism as an "acquisitive society" and demand in its stead a "functional society." The proponents of the existing order retort that business is a scheme of arrangements for producing goods "to satisfy wants"; income is contingent upon the performance of service, a person gets what he produces and must produce what he gets; and capitalism is a "functional society." The words "acquisitive" and "functional" are used with ease and defined with difficulty. A mediaeval chronicler writes: "The House of God is tripartite: some work, some fight, and some pray"; a modern expositor insists: "Economic society is composed of four groups: some work, some save, some provide land, and some undertake the risks of enterprise." An initial commitment and a selection of detail may indifferently make of an industrial order a functional or an acquisitive society. The exchange of arguments results in the statement rather than the answering of the questions: What are the functions needful to be performed and what is the scheme of control that gives greatest promise of performance?

The question of the role of acquisition in human affairs is not yet resolved. At present some hold that desire for money is rooted in a "human nature" which "cannot be changed"; they are confident that in the long run acquisition must be a means to social welfare, and would let matters alone. Others make selfish activity an expression of antisocial habits; they would have the individual charge his conscience with his duty to his fellow men, make of business a profession with its higher ethical code, and replace the urge toward gain with the spirit of service. Still others find self-love a useful human possession, neither good nor bad in itself; they would so make over the values, arrangements and usages of society that individuals in pursuing their own interests are impelled in the way of general welfare. Thus in programs aiming alike at the larger good, acquisition is to be left alone, suppressed, and directed. Amid the uncertain and changing values of life private gain and public good bid fair to present an abiding issue.

ACSADY, IGNAC (1845-1906), Hungarian historian and publicist. He was educated at Debreczin and Budapest, and in 1869 began his journalistic career as a contributor to the liberal political daily, *Szászadunk*; later he became a regular contributor to the *Pesti Napló*. With Charles Tagányi, Acsády was the founder of the modern school of Hungarian economic history. He made use of a great mass of unpublished archive material and was one of the first of the Hungarian historians to adopt the methods of the German *Kulturgeschichte*, a trend predominant in the last half of the nineteenth century. He specialized in the history of the sixteenth, seventeenth and eighteenth

centuries, dealing at length with the history of economic classes, of state finances and with population problems of Hungary. His essays on the history of financial administration are of particular merit and are especially brilliant in the treatment of the Hapsburgs.

ACTION FRANCAISE, a French political group, highly critical of democracy and republicanism and striving for the restoration of monarchy and the intensification of nationalism. It has grown out of the Ligue de la Patrie Française, a committee formed in 1898, in the midst of popular excitement about the celebrated Dreyfus case, by persons of conservative and militarist tendency who were violently anti-Dreyfusard. In 1899 Henry Vaugois, the leader in this movement, began the publication of the *Action française*, first as a weekly and after 1908 as a daily. Under the influence of its prominent intellectual leader, Charles Maurras, who joined Vaugois, and with the special financial backing of a large legacy from the widow of Marshal MacMahon, it gained the adherence of most French royalists, traditionalists and other ultra-conservatives, chiefly Catholic in religion, until it has become the outstanding expression of reaction in France. The central organization supports a number of dependent propagandist societies, as well as publications, for city and countryside, for students and professional men; the interesting "Camelots du Roi" are a body of young men who police the meetings and lead the street demonstrations of the Action Française.

The popular influence of the group is difficult to estimate. Its direct influence on French politics is certainly slight; not a single professed member of the organization now occupies a seat in the French Parliament, and only one

(Léon Daudet) occupied such a seat from 1919 to 1924. Indirectly, however, its influence is considerable. Not only have young persons, particularly university students, been attracted to it in increasing numbers, but many of its nationalist activities have been acclaimed by journalists and politicians who profess abhorrence of its royalist principles. On the other hand the organization has suffered internal schisms as well as external setbacks. Two of its leaders, Louis Dimier and Georges Valois, have left it as a result of internal dissensions, the former in 1920 and the latter in 1925. More recently, moreover, the Catholic church has officially opposed it.

The organization has catered to Catholics by denouncing the "anticlerical" legislation of the French Republic, and it is estimated that at least three quarters of its enrolled members have been Catholics, including many priests. Its chief director, Charles Maurras, is, however, a positivist and an agnostic and has expressed anti-Christian opinions in some of his books. This fact has recently been seized upon by the ecclesiastical authorities as justification for their condemnation of a movement which must have appeared to them as alienating republican Frenchmen from the church. On August 27, 1926, Cardinal Andrieu, Archbishop of Bordeaux, publicly condemned many of the teachings of the Action Française and counseled Catholics to withdraw from it, and his action was endorsed by Pope Pius XI on September 7, 1926; on December 29, the pope went further, forbidding Catholics to belong to it or habitually to read its literature. Almost the entire hierarchy of the Catholic church in France, by a circular letter of March 10, 1928, recorded their support of the papal position, while emphasizing its moral, rather than political, implications. Since then new dissensions have existed among French Catholics, between those who have obeyed the pope and those who have disobeyed him.

The doctrine of the Action Française is essentially that of Charles Maurras and represents a curious admixture of the positivism of Comte, the traditionalism of DeBonald and the *élan vital* of Bergson. It is summarized in three formulae: integral nationalism, practical empiricism and the forceful blow. "Integral nationalism" means that "a national policy should be pursued, involving the multiplication and strengthening of institutions which benefit the greatest possible number of living organisms

by maintaining national integrity and fostering the growth of national power (for a nation declines when it ceases to grow in power)." By "practical empiricism" is meant primarily the teaching that "order in society, no matter how it is obtained, is more important than the liberty of the individual." Concerning the "forceful blow," it is declared "that the supplanting of the republic by the monarchy (a condition necessary for the salvation of the country) will probably not be realized (unless extraordinary events occur) by the ballot, but rather that the existing government will be overthrown, like most preceding governments, by force; and that the preparation and organization of the needful *coup de force*, as well as the creation and diffusion of a state of mind which would assure success to the use of force, are essential and necessary elements of the program of the Action Française." The doctrine, as a whole or in its parts, seems to have elicited the sympathy of such different intellectual types as Maurice Barrès and Georges Sorel and has undoubtedly affected the thought of the younger generation in contemporary France, far beyond the enrolled membership of the organization. In particular the criticisms which it has leveled against individualism and democracy have been incisive and have contributed to the existence in France of an impatience with parliamentary republicanism akin to, though admittedly less influential than, that engendered by Fascism in Italy or by Sovietism in Russia.

The Action Française recognizes the Duke of Guise, the heir of the Bourbon and Orleanist families, as rightful king of France, and demands the restoration of the old monarchy with its supposedly traditional institutions and policies. The most important of these are regionalism, that is, local decentralization and some provincial autonomy within the country; a privileged position for the church and for the "syndicates" of social classes and economic groups; the substitution of a kind of syndicalism and functional representation for existing individualism and political democracy. The organization is militantly nationalist. Its tirades against Germany and its criticisms of the League of Nations are incessant. It preaches the necessity not only of adequate French security, but also of forceful French expansion in Europe and overseas. It perpetually accuses the French Republic of cowardice, if not of treason; and, since its condemnation by the pope, it has directed especially venomous attacks against what

it terms the pacifist pro-German and anti-French alliance of the papacy with the republican government of France.

ACTON, JOHN EMERICH EDWARD DALBERG, EIGHTH BARONET AND FIRST BARON (1834-1902), English historian. His education was remarkably cosmopolitan. As a boy he went to school in Paris; for five years he studied at the Catholic College of Oscott, in England, presided over by Dr. (later Cardinal) Wiseman; next he was tutored at Edinburgh by Dr. Logan; and thereafter for six years he resided at Munich as the guest, pupil and friend of the famous German historian Döllinger. He visited the United States in 1855, Russia in 1856, and Italy, in company with Döllinger, in 1857. To Döllinger's influence may be attributed Acton's subsequent devotion to scholarly erudition and to "scientific" history, to the ideal of exact and full truthfulness in historical investigation and writing. This ideal, together with a mastery of detail and a cosmopolitanism which made him master of many languages and at home in several countries, rendered Acton one of the outstanding scholars of his age. His amazing scholarship, moreover, he applied to causes which were always dear to him and which nicely reflected the spirit of the age; he was stalwartly liberal in politics, economics and religion; a foe of bigotry and persecution; an enemy of nationalism; and, although a practising Catholic to the day of his death, a severe critic of many papal policies.

In 1859 Acton settled definitely in England

and for the next six years was a member of Parliament for an Irish constituency, voting with the Liberals and forming a close friendship with Gladstone, but taking little part in the debates. In the meantime he began to sponsor and write a great deal for a series of Catholic reviews by means of which he hoped to promote critical scholarship among his co-religionists. The extreme liberalism of these journals, however, gave repeated offense to ecclesiastical authorities and led to the discontinuance of one after another: *The Rambler* (1859-62); *The Home and Foreign Review* (1862-64); *The Chronicle* (1867-68); and *The North British Review* (1868-71). Acton was bitterly hostile to Pope Pius IX's Syllabus of Errors of 1864, and in 1869-70 he zealously opposed the projected definition of the dogma of papal infallibility by the Vatican Council. It was on Gladstone's nomination that Acton was raised to the peerage in 1869, but he later took issue with Gladstone's interpretation of the decrees of the Vatican Council and in 1875 expressed his concurrence with Newman's views of papal infallibility. That closed the polemical period of Acton's career.

Acton helped to establish the *English Historical Review* in 1886. In 1895, on the nomination of Lord Rosebery, he was appointed Regius Professor of Modern History at Cambridge in succession to Sir John Seeley. During 1899-1900 he projected the *Cambridge Modern History* in twelve volumes, the first of a very noteworthy series of cooperative surveys of world history, written by acknowledged historical specialists of various countries, and he lived to see most of the first volume and half of the second in type. Acton himself never wrote a book. He gathered a good deal of material for monumental works on the history of freedom and on the French Revolution, but his absorption in detail and his lack of requisite organizing ability prevented him from bringing any of his larger plans to fruition. High historical ideals, a leading part in the dissemination of German methods of scientific history in England, and a few valuable essays and suggestive fragments which have been collected since his death in volumes mentioned below, were the legacy which Lord Acton bequeathed to contemporary social science.

ACTS OF TRADE, BRITISH. This term is used in a historical sense to designate certain statutes of the English Parliament, chiefly in the seventeenth century, passed in the interest of shipping, mariners and trade. As commerce began to expand during the last days of Elizabeth's reign and the early years of the reign of James I, and as colonization became significant in the period before the Civil Wars, rules were laid down, characteristic of all the maritime states of Europe at the time, for the control of trade and the plantations. England had already defined her position in regard to the carrying trade in certain experimental and temporary statutes of Richard II, Henry VII and Elizabeth, whereby certain valued commodities were to be imported into England from the continent in English ships manned for the most part by English sailors. Moreover, in 1621, after the settlement of Virginia and Bermuda, the Privy Council extended the rule by ordaining that plantation commodities—in this instance tobacco—should be “appropriated unto his Majesty's subjects and not communicated to foreign countries but by way of trade and commerce and from hence only,” inasmuch as they were English colonies and it was the custom of all colonizing countries to keep their plantation trade to themselves.

After the decade 1630–40, when the Dutch had succeeded in obtaining almost complete control of the carrying trade of the world, the Rump Parliament, partly in a spirit of retaliation and partly for the purpose of managing England's trade to her best advantage, in 1651 passed an ordinance of the Commonwealth commonly known as the first navigation act. By this ordinance all plantation commodities of Asia, Africa and America and all goods of the growth and manufacture of Europe were to be imported into England, Ireland, Wales,

Berwick-upon-Tweed and other English possessions only in ships owned, commanded and manned by English subjects of the Commonwealth or, in the case of European goods, in such ships as belonged to the people of the country whence the cargo came or where it was produced or to people resident in the port of first shipment. This act, which was clearly designed to injure the Dutch carrying trade, was probably passed at the instigation of a few interested London merchants belonging to the East India and Levant Companies. It did little to impair the dominance of the Dutch in the commercial world, for they were almost as powerful in 1675 as they had been in 1650, and it undoubtedly hurt rather than helped England's trade as a whole.

Owing to the maladministration of the finances under the Commonwealth and the Protectorate, England in 1660 was on the verge of bankruptcy, with a debt estimated at £3,000,000—more than double the largest recorded crown liability before 1641. Trade was depressed and the merchants were filled with foreboding. On the restoration of Charles II the revival of trade became a matter of first importance to the king and Lord Chancellor Hyde (afterwards the Earl of Clarendon) as well as to both merchants and officials. Before the end of the year a council of trade and a council for foreign plantations were set up, and on September 17 the Convention Parliament passed an act—confirmed by the regular Parliament the next year—for the encouragement and increase of shipping and navigation. In its first seventeen clauses this act repeated the essential features of the ordinance of 1651 (which ceased to have validity on the return of the monarchy), differing from it only in one or two particulars. It removed all restraints upon the trade with continental Europe, except Russia and Turkey, but required that all plantation commodities brought into England be brought only in English built ships (foreign built ships were debarred by an act passed the next year), owned by Englishmen and properly certificated and registered, of which the masters and three fourths of the seamen should be English subjects. The Channel Islands, Scotland, construed as a stranger kingdom until 1707, and Ireland by a later act of 1671 were denied the privileges of this act. Its language, as well as that of subsequent acts, was so poorly chosen that many difficulties arose in the attempts that were made at enforcement. In some

cases decisions were not reached throughout the eighteenth century, and customs officials, both in England and the plantations were often perplexed as to what to do. They generally construed the acts as literally as possible, and in some cases of doubt threw the ultimate decision upon the treasury, the commissioners of the customs and the law officers of the crown.

The eighteenth clause of the act of 1660 revived a regulation that does not appear to have been enforced under the Puritan administration—the requirement that certain plantation commodities be brought to England only. The order in council of 1621 had required that “all tobacco and other commodities whatsoever” should be brought directly to England; the act of 1660 was not so sweeping, enumerating only sugar, tobacco, cotton-wool, indigo, ginger and such dyewoods of plantation growth as fustic, braziletto and logwood. In the following century the list was extended to include many other commodities that England wanted and valued, partly for promoting her shipping and manufactures, as in the case of naval stores, iron, copper and lumber, partly for purposes of revenue, as in the case of rice, and partly to injure France, as in the case of beaver and other furs and also of molasses. After 1764 the list was still further extended, and finally concerned the northern colonies as well as those of the south and the West Indies. In 1730 and 1735 rice, and in 1739 sugar, were in part relieved of the restraint, and eventually rice was allowed to be shipped to any point in Europe, Africa and America south of Cape Finisterre. It was always a debatable point whether coconuts, logwood from Honduras and Canary wines were enumerated or not. The customs officials said that they were; the law officers were inclined to think that they were not.

After the act of 1660 had been in operation for ten years it was discovered that the colonists were evading it in one important particular. Since enumerated commodities could be carried from one plantation to another, for the benefit of the colonists, New Englanders and New Yorkers thought staples thus carried and not consumed in the plantations had fulfilled the law and could be reshipped to Europe. This practise, which broke through the intended channel of trade and led to the diminution of the English customs revenue, called for further legislation. An act was passed in 1673 which contained a clause declaring that all vessels arriving at the plantations and intending

to take on a cargo of enumerated commodities should pay a duty at the colonial port of clearance, unless their captains could show the governor (or later the naval officer or the royal collector) a certificate that they had given bond in England to carry their lading directly back to the mother country. This payment, which came to be known as the “plantation duty,” was a penny a pound on tobacco and other sums for other enumerated commodities. Even if the captain paid the duty he was still obliged to deposit a bond with the governor, naval officer or collector, binding himself, if he did not unload the goods at another colonial port, to take them directly to England, where he would still have to pay in addition the usual customs duty.

Thus far the acts regulated the plantation trade in only one direction, that toward England. In 1663 an act was passed regulating the trade the other way, that is, from Europe to America, by requiring that all foreign goods wanted by the colonists must first enter at an English port and thence be shipped to America as if they were English goods. The idea was to make the realm—that is, England, Wales and Berwick-upon-Tweed—the center, staple and magazine of all commodities exported from or imported into the plantations. The purpose of the act was to augment the revenue and the carrying trade and also to maintain a better correspondency with the king’s subjects across the sea, to keep them in a closer dependence on the mother country and to render them more beneficial and advantageous to her, objects frequently mentioned in the acts.

Owing to the many ambiguities found in these acts and to the fact that they were continually violated in the years before the Revolution of 1689, despite strenuous efforts on the part of the treasury and the commissioners of the customs to see that they were enforced, a final act was passed in 1696 as part of a general attempt of the government to make the whole system more rigid. Although this act made a number of important changes in phraseology and introduced many new details in matters of administration, it did not alter in any essential particular the rules laid down by the acts of 1660, 1663 and 1673. It increased the number of ambiguities, extended considerably the machinery of operation, provided for vice-admiralty courts, and granted greater powers to the customs officers in the colonies. A number of explanatory and supplementary acts were passed in the

eighteenth century, the most important of which was the Molasses Act of 1733, which vainly attempted to regulate the trade between the British northern colonies and the French and other foreign colonies in the West Indies. But no acts, proclamations or orders in council, of date later than 1663, changed in any way the fundamental principles upon which the navigation acts were based.

The objects of the acts were to increase England's shipping and to create for her an advantageous trade. An advantageous trade was one which encouraged navigation and added to the number of England's seamen; which exported England's products and manufactures and imported those raw materials that England needed either for consumption or to use in her industries or for the fitting out of her ships engaged in domestic and foreign trade; and which created a general balance of exports over imports in England's favor. The ultimate object was to render the realm the chief beneficiary of all commercial operations in which the British world was engaged. To this end the welfare of Scotland, until 1707, Ireland and the plantations was sacrificed in the interest of the leading partner, for the conviction was firmly held that an independent trade for any of the subordinate members would be injurious to the trade of the realm and would violate wholly the purposes for which such dependents existed. Of all the plantations settled by the English, Ireland was considered most inimical to England's prosperity and in the long run suffered more from the navigation and other acts than did either the Channel Islands or the American plantations. For her treatment of Ireland England was to suffer a heavy reckoning in the nineteenth and twentieth centuries.

In the American colonies the effects of the acts of trade were less conspicuous. Although the acts were restrictive, in the sense that they confined trade to English and colonial bottoms and endeavored to direct and protect the channels through which the plantation trade was to flow, it may be doubted whether they ever were a serious menace to colonial development. That inconvenience and loss were caused in many instances is doubtless true; but in time the colonists adjusted themselves to the conditions, and in the eighteenth century had largely ceased to find fault, except perhaps in the British West Indies, where the acts were a greater hardship than on the continent. But even there other causes must be assigned for the general decline.

Where the acts manifestly worked an injury they were moderated, as in the case of rice and sugar and of the Greenland fishery and the Baltic trade; or they were successfully evaded, as in the case of the Molasses Act; or they were neutralized by smuggling and by the connivance of customs officials in America. The attempts to interfere with colonial freedom of commerce were much less significant in causing the revolt of the colonies than were the attempts of the British authorities to interfere with colonial legislation and the exercise of colonial self-government. In this respect the causes of the revolution were political rather than commercial.

How far the acts of trade were of advantage to England herself will always be a matter of speculation. Contemporary writers were not agreed as to their merits and many were strongly opposed to them, believing that they seriously injured England's own freedom of commercial action. Others, particularly of a later date, called them England's "Magna Charta Maritima" and "Commercial Palladium," and attributed her naval supremacy and commercial leadership to their influence. After 1783 the general situation was so far changed as to require their frequent suspension and they were greatly modified under Huskisson's influence in 1822 and 1823. The last navigation act was passed in 1845 and the final repeal took place four years later. England lost in consequence nothing of her naval importance or commercial prosperity, and there is reason to believe that the beneficial effects of the acts of trade upon England's own growth and expansion have been unduly exaggerated.

ACTUARIAL SCIENCE. *See* LIFE INSURANCE.

ACWORTH, WILLIAM MITCHELL (1850-1925), railway economist. He was graduated from Oxford in history and for a time served as English tutor to the ex-Kaiser and his brother. Later he became a master at Dulwich College, but in 1885 he gave up scholastic life. He was chairman of the Metropolitan Asylums Board and a member of the London County Council, and in 1890 was called to the bar. Railways became his paramount interest. *The Railways of England* (London 1889) and *The Railways of Scotland* (London 1890) led to a visit to America for the study of American railroad practise, of which he ever remained an admirer. In *The Railways and the Traders* (London 1891) he attacked the secrecy of British railway accounts, and fearlessly continued the fight until ton and passenger-mile statistics were achieved (1920). His lectures for railway students were embodied in his *Elements of Railway Economics* (Oxford 1905, revised Oxford 1924), which launched that subject in England. As a member of the Royal Commission on Accidents to Railway Servants (1899), the Vice-Regal Commission on Irish Railways, the Board of Trade Committee on Railway Accounts and Statistics (1906) and as a barrister at the parliamentary bar specializing in railway work, he amassed an unequalled knowledge of railway history and practise. Impartiality and sound judgment enabled him later to make much use of this knowledge.

Criticism of British methods alienated British railwaymen, but his reputation as a railway expert grew elsewhere. After 1915 his main work was abroad. His evidence before the Newlands Committee of Congress (1917) formed the basis for *An Historical Sketch of State Railway Ownership* (London 1920). Although he was opposed to the principle of state ownership he recognized its occasional use. As one of a commission of three he was largely responsible for the Canadian National system. His reports upon the railways of southern Rhodesia (Salisbury 1918), India (London 1921), Austria, undertaken for the League of

Nations (Geneva 1923) and Germany, for the Reparations Commission (London 1924), materially affected social and industrial progress in those countries. He was a member of the Railway Rates Advisory Committee (1919-20). On his deathbed he was arranging details of an inquiry into the railways of Rumania. Acworth's great contribution to society was the instigation of a new relationship between a nation and its railways, by which he endeavored, successfully, to coordinate the benefits of government and private ownership.

CHARLES ELY ROSE SHERRINGTON

Consult: Stephenson, W. T., "Sir William Acworth" in *Economic Journal*, vol. xxxv (1925) 327-29; Paish, G., "Sir William Mitchell Acworth" in *Journal of the Royal Statistical Society*, n. s., vol. lxxxviii (1925) 467-70.

ADAMS, BROOKS (1848-1927), social theorist, brother of Henry Adams, undertook to extend to social processes the physical principle of the dissipation of energy. In *The Law of Civilization and Decay* (London 1895; 2nd ed. New York 1897) he held that societies dissipate their energies in movement and centralize as they accelerate. In *The New Empire* (New York 1903) he attempted to discover the laws of consolidation and dissolution of those administrative masses called empires, holding that the economic center of the world determines the social equilibrium, and that this international center of exchange is an ambulatory spot on the earth's surface, which shifts back and forth as discoveries in applied science and geography change avenues of communication and cause trade routes to converge. Adams wrote in *The Theory of Social Revolutions* (New York 1913) that consolidation implies equivalent capacity for administration, but since adaptation to changing demands of the environment is beyond an established type of mind, new governing classes arise until the limit of the administrative capacity of the race is reached, and disintegration begins. The rise of a new governing class is always synonymous with a social revolution and the redistribution of property. In his introduction to Henry Adams' *The Degradation of the Democratic Dogma* (New York 1919) he likened modern democracy, with its infinite mass of conflicting minds and interests, to a vapor which loses in collective intellectual energy in proportion to its expansion. Brooks Adams had great vigor of thought and expression, but probably his chief contribution

was in stimulating his brother Henry's speculations on a science of history.

HAROLD D. LASSWELL

ADAMS, CHARLES FRANCIS (1807-86), American diplomat and statesman. In 1840 he began his inevitable political career as Whig member of the Massachusetts legislature. He was essentially the balanced, moderate, instructed statesman, and slavery moved him, not to abolitionism, but into the ranks of the "Conscience Whigs." In 1848 he was nominated for the vice presidency by the Free Soilers. In 1859 he was elected to Congress by the Republicans.

His flawless record as minister to Great Britain during the Civil War constitutes his claim to fame. He did not, perhaps, embody the qualities of a constructive diplomat, but he knew his trade, and he represented the United States with a bold and honorable mien which won increasingly the respect of the British. The details of his mission are national history.

Returning to the United States in 1868, he declined the presidency of Harvard and escaped that of the United States. The chief Liberal Republican leaders were anxious to name him to run against Grant in 1872, and the Democrats were willing to endorse him. The convention, however, was stampeded for Horace Greeley, whose overwhelming electoral defeat is slight indication of how Adams might have run. During these uncertainties Adams was performing the most important service of his life. As United States arbitrator for the Geneva arbitration, he devised a method of disposing of the hopeless American claims for indirect damages, which saved the arbitration and its subsequent prestige.

Important works: *Life of John Adams*, 2 vols. (Philadelphia 1871); an introductory "Memoir" to Adams, Abigail, *Letters*, 2 vols. (2nd ed. Boston 1840) vol. i, p. xiii-lxxxvi. He edited his father's *Memoirs*, 12 vols. (Philadelphia 1874-77), and a number of his letters are reprinted in *A Cycle of Adams Letters, 1861-1865*, ed. by W. C. Ford, 2 vols. (Boston 1920).

Consult: Adams, Charles Francis, Jr., *Charles Francis Adams* (Boston 1908); a compendious life is in preparation.

ADAMS, CHARLES FRANCIS (1835-1915), American economist and historian, brother of Henry Adams. After thirty-six years of rather casual existence he centered his attention on the study of railroad questions. Partly by way of providing a congenial place for himself in the life of his day he advocated the creation of the

Massachusetts Board of Railroad Commissioners, of which he was a member for ten years from its inception (1869). President of the Union Pacific from 1884 to 1890, he continued for many years to head the Kansas City Stockyards Company, and speculated to advantage in Kansas City real estate. He recorded convictions on a variety of governmental and educational problems.

In general a believer in the efficacy of competition as a regulator of industry, with respect to railroads Adams early pointed out that it resulted in instability of rates at common points and extortion elsewhere. He was reluctant to accept government regulation as an alternative, underestimating, perhaps, its administrative possibilities. The effectiveness of the partial public ownership which he proposed instead—as a means of diffusing standard practises—has remained problematical. An Easterner of property, with Western interests of the kind noted, he indignantly defended judicial review of state rate-making. "Bad manners" and local discrimination, he thought, had brought down upon the railroad companies the blame for conditions attributable to "protection and paper money" or to the carelessness of settlement in the West.

The historical work of Adams was to some extent directed by his public and ancestral connection with Quincy, Mass., and by the service of his father as minister to England during the Civil War. His New England studies rest upon a general understanding of the period and a critical sense of cultural values. They exhibit an interest not merely in political development but in social relations, manners and modes of life. The investigations in diplomacy dramatically visualize the uncertainty of events. An essay on "The Era of Change" is a brilliant speculative example of economic determinism.

Adams was a diverting analyst of railroad finance in the buccaneering period. A flexible sense of humor and a forceful epigrammatic style mark his writings.

THOR HULTGREN

Important works: *Chapters of Erie and Other Essays*, with his brother (Boston 1871); *Railroads, Their Origin and Problems* (Boston 1878, revised ed. 1886); *Notes on Railroad Accidents*, lucidly analytical (New York 1879); *Three Episodes of Massachusetts History* (Boston 1892); *Studies, Military and Diplomatic* (New York 1911). Aside from *Charles Francis Adams, an Autobiography* (Boston 1916) there is no substantial account of his life and work.

ADAMS, GEORGE BURTON (1851-1925), American historian. Like other American scholars of the period he received his graduate training in Germany (Ph.D. Leipsic, 1886) where he was especially influenced by the seminar method of Wilhelm Arndt which had been derived through Waitz from Ranke. As occupant of the chair of history at Yale (1898-1917) and as one of the organizers of the *American Historical Review* (1895) he was influential in applying to American scholarship the premises and animus of the German historical discipline.

Adams was probably led into the field of English constitutional history by his early interest in feudalism, shown, for example, in his well known *Civilization during the Middle Ages* (1894). He found the feudal period and the fact of feudalism to have been crucial in the development of the English constitution, and in the working out of that idea lies his creative achievement. He traced the development of English central government from the absolutism of the Norman monarchy to its present democratic results; the central fact in this process was the dominance of law over the king; the point where this dominance was decisively asserted was the Magna Carta in 1215; the vehicle for its assertion lay in the feudal character of that document—its identification of opposition to absolutism with the hallowed traditional forms of a disappearing feudalism.

At other points also Adams contributed to the scholarship of English constitutional history: the early history of Parliament, the splitting off of English and American democracies from the main trunk of the English constitution, the importance of the cabinet system, the effect of monarchic forms upon democratic actualities and the early history of councils and courts.

A dignified, graceful style and a substantial erudition made Adams a respected figure in the scholarly world. For a while he was a little troubled by the encroaching conception of history as a more complex and elusive process than it had been to the school in which he was trained. But in the main he rested in the conviction, expressed in his presidential address to the American Historical Association in 1908, that "history has been determined by forces which act according to fixed law."

MAX LERNER

Important works: *Civilization during the Middle Ages* (New York 1894); *The Growth of the French Nation* (Meadville, Pa. 1896); "Origin and Results of Imperial Federation Movement in England" in *State*

Historical Society of Wisconsin, Proceedings, vol. xlv (1899) 93-116; *Select Documents of English Constitutional History* (with H. Morse Stephens) (New York 1901); "The History of England from the Norman Conquest to the Death of John (1066-1216)" in Hunt, W., and Poole, R. L., *Political History of England*, 12 vols. (London 1906-10) vol. ii; *The Origin of the English Constitution* (New Haven 1912); *The Constitutional History of England* (New York 1921); *Council and Courts in Anglo-Norman England* (New Haven 1926).

ADAMS, HENRY (1838-1918), historian, grandson of John Quincy Adams and third son of the older Charles Francis Adams. He was born in Boston, graduated from Harvard College in 1858, went to Berlin to study civil law, listened to one lecture, spent two years wandering about Germany and Italy, and for want of something better to do became private secretary to his father, who was ambassador to Great Britain during the Civil War. He returned home with the vague intention of entering journalism on behalf of political reform. Disillusioned by the announcement of Grant's cabinet, he accepted an unsolicited appointment as assistant professor of history at Harvard (1870-77), where he imposed upon a few exceptional students a drastic training in historical research, the result of which was a volume of studies (*Essays in Anglo-Saxon Law*, Boston 1876) containing one by Adams himself on "Anglo-Saxon Courts of Law." During the years 1875-76 Adams was also editor of the *North American Review*. After retiring from Harvard Adams resided in Washington but spent much time abroad, especially in Paris, and although counted something of a recluse numbered among his friends and acquaintances many of the most distinguished persons of his generation.

Adams' career falls into two periods. Until about 1895 he was occupied chiefly with the study of American history, although he wrote also *Democracy, An American Novel* (London 1882). Besides special articles, *Historical Essays* (New York 1891), the results of these studies were: *Documents Relating to New England Federalism, 1800-1815* (Boston 1877); *The Life of Albert Gallatin* (Philadelphia 1879); *John Randolph* (New York 1882); *A History of the United States from 1801 to 1817*, in nine volumes (New York 1889-91). In recognition of the high quality of these works, Adams was chosen president of the American Historical Association (1894). The short address which he wrote (but was not present to deliver) for his inau-

guration shows, however, that he had already become skeptical of the value of writing history as he and his colleagues were writing it. During the second period of his life he therefore wrote no more history in the ordinary way, unless one should except the biography written for friendship's sake, *The Life of George Cabot Lodge* (New York 1911). For twenty years he was, on the surface at least, an amused and disillusioned observer of the human scene, engaged in what he ironically called the "search for an education." One may suppose, however, that underneath his sardonic humor Adams was seriously seeking for the significance of his own life and the life of humanity. What troubled him was the fact that a man of his opportunities and ability had been able to accomplish, as he saw it, nothing really memorable or important. The search for an education was therefore an attempt to discover the reason for his failure, to discover the "lines of force" that dominated his age, to discover, in a word, the secret of social evolution, a science or philosophy of history. His later works are largely concerned with this recondite problem: *Mont Saint Michel and Chartres* (p. p. Washington 1904, pub. New York 1913); *The Education of Henry Adams: An Autobiography* (p. p. 1906, pub. Boston 1918) a sequel to the *Mont Saint Michel*; *A Letter to American Teachers of History* (p. p. Washington 1910); *The Degradation of the Democratic Dogma* (New York 1919), which contains the "Letter to American Teachers of History" and "The Rule of Phase Applied to History."

What chiefly troubled Adams was that his own achievements, whether worth while or not, seemed to be the result of accident rather than of purpose; and, so far as he could see, his own life was typical of that of humanity which, conscious of purpose, appeared nevertheless to be driven forward by blind forces which could be neither anticipated nor controlled. Far from solving this problem, Adams never succeeded even in stating it to his own satisfaction. After 1914 he therefore wrote nothing, judging that next to good humor silence was the chief mark of sense. The publication of his privately printed works was contrary to his expressed judgment, but it would be rash to say contrary to his secret desire. Adams will be known chiefly for his *History of the United States*, which is probably one of the ablest works produced by an American historian, and for his *Education of Henry Adams*, undoubtedly one of the most

remarkable autobiographies in the language.

CARL BECKER

Works: The chief sources of information are the writings of Adams mentioned above, especially the *Education of Henry Adams*. In addition should be noted *A Cycle of Adams Letters, 1861-1865*, ed. by W. C. Ford 2 vols. (New York 1920), and *Letters to a Niece and Prayer to the Virgin of Chartres* (with *A Niece's Memories*, by Mabel La Farge) (Boston 1920).

Consult: Taylor, H. O., "The Education of Henry Adams" in *Atlantic Monthly*, vol. cxxii (1918) 484-91; Becker, Carl, "The Education of Henry Adams" in *American Historical Review*, vol. xxiv (1919) 422-34; More, P. E., "Henry Adams" in *Unpopular Review*, vol. x (1918) 255-72.

ADAMS, HENRY CARTER (1851-1921), American economist. His parents, who were of old New England stock, had settled as missionaries in Iowa in 1842. His antecedents and early training pointed to a career in the church, and in 1875 he entered Andover Theological Seminary. He was quickly convinced, however, that "clear thinking is more important than effective exhortation," and began to envisage a life of intellectual activity, with special reference to social and economic science. An opportunity for graduate study presented itself at the newly organized Johns Hopkins University, from which he received one of its first doctorates in 1878. Then followed a brief period at Oxford, Paris, Berlin and Heidelberg for the completion of his formal training, and in 1879 he was initiated into his academic career at Cornell University. In 1886 he was dismissed from Cornell, in direct consequence of a frank expression of his views on the labor problem. From 1887 until his death he held the chair of political economy at the University of Michigan.

His distinctive importance in the field of social science lies in his pioneering efforts, among Americans, as an investigator of the province of government in economic affairs and as an active agent in its development. His contributions along these lines, particularly through his long service with the Interstate Commerce Commission, have exerted a potent influence upon the prevailing principles and practises of public control.

In the beginning of his career Adams' major inquiries were largely in the realm of public finance. His doctoral dissertation on the history of American taxation was followed by a book on public debts which has since become a classic. His keenly analytic *Science of Finance* was the first comprehensive treatise on public finance

by an American. He rendered his most enduring service in the sphere of public control of private enterprise. His monograph on the relation of the state to industrial action was a forerunner of much of the theoretical speculation from which the emerging period of governmental intervention drew its impetus. Imbued with the necessity of subjecting economic institutions and their concrete manifestations to the test of ethical standards and social consequences, he pointed out the shortcomings of unrelieved laissez-faire doctrine and developed guiding principles for the assertion of state power. To these basic problems of public control he returned again and again in his subsequent writings; and he also found himself in a position to exert practical influence upon their solution.

Through public service in the statistical and accounting field he was enabled to develop concrete institutional arrangements for railroad control. Beginning in 1888 he served the Interstate Commerce Commission, in charge of statistics and accounts, for a period of more than two decades. Recognizing from the first the supreme importance of full, accurate and comparable data as a basis for effective railroad regulation, he sought to make the required reports of the carriers as informative and reliable as possible. Despite grave obstacles significant improvement was achieved. By the statutory amendments of 1906 the carriers were required to submit their reports under oath, and the commission was empowered to prescribe uniform accounting systems and to enforce compliance with its prescribed requirements. Adams played an influential role in securing this strengthened legislative structure, and he was the central figure in developing the classifications and regulations in pursuance thereof. Cooperating for a number of years with the Committee of Twenty-Five of the American Railway Accounting Officers' Association, he succeeded in evolving a uniform system of accounts which constituted the first mandatory regulations for the steam railroads of the United States. While many of these original classifications have been superseded, and new accounting and statistical expedients are constantly emerging, the basic principles established by these classifications have largely survived. In its fundamentals, moreover, this system has been extended to other carriers subject to federal jurisdiction, and has been widely adopted in the regulation of local utilities. The strongest evidence of Adams' influence is found in the universal

acceptance of such prescribed accounting and statistical practise as an indispensable instrument of public control.

I. L. SHARFMAN

Important works: "Taxation in the United States, 1789-1816," *Johns Hopkins University Studies in Historical and Political Science*, vol. ii (1884) 263-341; *Public Debts* (New York 1887); "Relation of the State to Industrial Action" in *American Economic Association, Publications*, vol. i (1887) 465-549; "Economics and Jurisprudence" in *American Economic Association, Economic Studies*, vol. ii (1897) 1-48; *The Science of Finance* (New York 1898); *American Railway Accounting* (New York 1918).

Consult: Bigelow, S. L., Sharfman, I. L., and Wenley, R. M., "Henry Carter Adams" in *Journal of Political Economy*, vol. xxx (1922) 201-11, including a complete bibliography of his works; "Memorial to Former President Henry C. Adams" in *American Economic Review*, vol. xii (1922) 401-16.

ADAMS, HERBERT BAXTER (1850-1901), American historian. He was graduated at the head of the class of 1872 at Amherst College, studied in Germany, and in 1876 received the degree of Doctor of Philosophy at Heidelberg. He then went to Johns Hopkins University as one of its first group of fellows, soon began teaching there, and was successively associate professor and professor of history. In the seminar which he established he turned attention first to the study of the history of local government in America. The relations of church and state were also a favorite field of study with him. His strength, however, lay in organization rather than in research, and he deliberately chose to occupy himself with the building up of what became in his time the largest department of history in any American graduate school, instead of with historical writing. His only long book was *The Life and Writings of Jared Sparks* (2 vols., Boston 1893). Earlier he had broken new ground by founding the series of *Johns Hopkins Studies in Historical and Political Science*, and had written much on American educational history. His service to historical study in America lay not in doctrine but in the training and inspiring of a large proportion of the conspicuous historical scholars of the new generation, and especially in the organization in 1884 of the American Historical Association, of which he was the secretary until 1900 and the chief motive power from its foundation to his death.

J. F. JAMESON

Consult: "Herbert B. Adams, Tributes of Friends"

in *Johns Hopkins University Studies in Historical and Political Science*, extra vol. xxiii (1902), where a complete bibliography is given.

ADAMS, JOHN (1735-1826), lawyer, scholar, second president of the United States (1797-1801). He aided the cause of independence in Congress and helped draft the Declaration of Independence. It was as an apostle of equality and the rights of man that he expounded in *Thoughts on Government* (Philadelphia 1776) a liberalism tempered by a firm belief in checks and balances. He helped negotiate peace with England in 1783 and served as minister to England (1785-88). The disorders of the "critical period" following upon peace changed him into a conservative, and in *A Defence of the Constitutions of Government of the United States of America* (3 vols., London 1787-88) and *Discourses on Davilla* (Boston 1805), published originally in *The Gazette of the United States* (Philadelphia, April 28, 1790-April 27, 1791), he appears as our ablest defender of aristocracy. Discarding his early belief in the equality of man, he urged that government, though necessarily based upon popular sovereignty, must be administered by the rich, well-born and capable, under a system of checks and balances which would prevent the tyranny of majorities. He favored life tenure for office holders and a hereditary titled nobility. He served as vice president during the two Washington administrations and assumed the presidency in 1797, the exponent of a conservative New England Federalism and the leader of a badly divided party. While able, honest and fearless, his irascibility, stubbornness and want of tact rendered him unequal to the task of uniting the Federalists in the face of Hamilton's bitter enmity, or of saving them from blunders which caused their defeat at the end of his term. He rated among his greatest achievements the preservation of peace with France in 1798, and the appointment of John Marshall to the chief justiceship in 1801.

ROBERT E. CUSHMAN

Works: *Works*, ed. by Charles Francis Adams, 10 vols. (Boston 1850-56).

Consult: Adams, J. Q., and C. F., *Life of John Adams*, 2 vols. (Philadelphia 1871); Morse, J. T., Jr., *John Adams* (Boston 1884); Morse, A. D., "The Politics of John Adams" in *American Historical Review*, vol. iv (1898-99) 292-312; Merriam, C. E., *History of American Political Theories* (New York 1903) ch. iii; Walsh, C. M., *The Political Science of John Adams* (New York 1915).

ADAMS, JOHN QUINCY (1767-1848), American statesman and diplomat. He was the son of John Adams, second president of the United States. His public service began, after education at Harvard and travel abroad, when he was appointed in 1794 minister to the Netherlands and in 1797 to Prussia, with special commissions to Great Britain. He was retired upon Jefferson's taking office, and in 1802 elected senator from Massachusetts. Before his term was over he had become a Republican, and in 1809 he was made minister to Russia. He served as chief of the peace commission at Ghent, as minister to Great Britain, and from 1817 to 1825 as secretary of state. From 1825 to 1829 he was president of the United States.

Up to this point Adams was perhaps the most complete and ardent champion of American rights and American destiny. He upheld the violent action of Andrew Jackson in Florida, annexed that region and others to the west of it, and sought the acquisition of Cuba and Texas. He violently attacked the attitude and conduct of Great Britain, and was chiefly responsible for the formulation of the Monroe Doctrine, which was in large measure directed against that country. On domestic questions he was a nationalist, favoring a protective tariff and public works. But after his election to Congress in 1831, upon his retiring from the presidency, his interest came to center more and more on opposition to slavery, resulting in his wide popularity in the North as defender of the "right of petition." He was led also to reverse his former position on national expansion. Although he continued to be an independent he developed political connections with the Anti-Masonic, the National Republican and the Whig parties. He remained a member of Congress until his death in 1848.

His boundless vitality sought many other outlets. In 1806 he accepted a professorship of rhetoric at Harvard, and his published lectures did much to encourage the outburst of oratory which characterized the next generation. As secretary of state he edited, or supervised the editing of, many state papers which have proved foundation stones for our study of American history. One of his most important acts was to utilize the Smithsonian bequest for the creation of the institution bearing that name. His very numerous writings include state papers, a great many occasional publications, and more elaborate works, such as his lectures on rhetoric, his

lives of Madison and Monroe, and his books describing his travels in Silesia. Perhaps his most important work is his *Memoirs*, comprising extracts from his diary from 1795 to 1848, edited by C. F. Adams (12 vols., Philadelphia 1874-77). His *Writings*, covering the period from 1779 to 1823, are edited by W. C. Ford (7 vols., New York 1913-17).

CARL RUSSELL FISH

Consult: Morse, J. T., *John Quincy Adams* (Boston 1909); Ford, W. C., and Adams, C. F., *John Quincy Adams* (Cambridge, Mass. 1902).

ADAMS, SAMUEL (1722-1803), American statesman, cousin of John Adams. He was born in Boston and educated at Harvard (A.B. 1740; A.M. 1743). He inherited from his father Samuel a fair estate which he soon lost through neglect and mismanagement. Politics was his chief interest and after 1764 his only occupation. Skill as a political organizer and as a polemical writer gave him the leadership of the radical party. He was a member of the Massachusetts House of Representatives (1765-74), and as clerk (1766-74) wrote most of its state papers. He was one of the chief organizers of the opposition to the Stamp Act and the Townshend Acts, and by inflaming the popular dislike of the troops was a prime influence in bringing on the "Boston Massacre" (1770). When the controversy everywhere abated (1771-73), Adams revived it by his persistent attacks on Hutchinson, whom he regarded as a pliant tool of ministers. He organized the Massachusetts committees of correspondence to protect American rights (*Writings*, vol. ii, p. 348-50) when most people supposed they were at last secure. By some oversight he failed to foresee the importance of the Tea Act, but when the tea arrived he directed the opposition which ended by throwing it into the harbor (Wells, vol. ii, p. 110 *et seq.*). Adams was at first opposed to the belief that a continental congress would be the best means of supporting Massachusetts against the Coercive Acts (*Writings*, vol. iii, p. 115), fearing that it would prove too conciliatory, but he supported it eagerly when it was apparent that one would be assembled (*Ibid.*, vol. iii, p. 126). As a member of the Continental Congress (1774-81) he worked effectively for the passage of a series of resolutions known as the Association, was an early advocate of separation, signed the Declaration of Independence, and served on the committee to draft the Articles of Confederation. In 1779 he was one of the committee

that drafted the Massachusetts constitution, and author of its bill of rights. He at first opposed the adoption of the federal constitution, but was induced by clever manoeuvres to support it on condition that a bill of rights be added (Wells, vol. iii, p. 248, 260). He joined the Democratic-Republican party, served as lieutenant-governor of Massachusetts (1789-94), and as governor (1794-97).

Adams' effective work ended with 1776. Essentially a *frondeur*, he was never effective and rarely happy except in opposition. Skilled in the tactics of undermining authority, he was of little use in building it up. As a polemical writer his adroitness was all in attributing sinister motives to his opponents, while investing his own activities with a flavor of disinterested service in the cause of humanity. In political and religious faith, in the naive doctrinaire outlook of a limited but acute mind, in a genuine passion for liberty, Adams was representative of his century. Like Saint-Just and Robespierre, he loved humanity but suspected most men; and if, like Siéyès, he had mastered the science of politics, it was only because, like Madame Roland, he identified the activities of real men with abstract propositions about them.

ADAPTATION. The lack of precision in the use of this term in biological and sociological literature is due to the fact that it designates both a process and a state. It most frequently signifies those processes whereby a living organism is fitted to its physical and organic environments. The adaptive processes result in such modifications of structure and function as will facilitate growth and reproduction under the given conditions. The term "adaptation" is also used to indicate the end result of such modifications, or the state of being adapted. In this latter sense it is equivalent to "adjustment," or such harmonious relationship between organic traits and essential conditions of life as to

insure survival of the type. In the social sciences adaptation is used in both senses, though most commonly in the former. The term "accommodation" is also used to designate that part of the adaptive processes whereby conflicts are resolved and conflicting elements brought into a state of mutual toleration and hence of cooperative functioning. Conflict, competition, rivalry and emulation are as much parts of the processes of adaptation of individuals and groups to each other as are mutual aid and cooperation.

The modern uses of the term mark a revolution in scientific and philosophical thought. The theologians had found in the marvelous adaptations throughout nature most convincing evidences of an Omnipotent Designer of the universe. The biologist sought a naturalistic explanation of such harmonious interrelations. Lamarck found it in the inheritance of acquired characters, a doctrine now seen to be of limited value, if not wholly untrue. Darwin found it in the combined effects of variation, selection and heredity. He found that those variates of any plant or animal which more nearly fit the environment tend to live longest and leave most progeny. As Spencer said, there is a "survival of the fittest." Through inheritance their traits become more and more general, thus producing a progressively more perfect adaptation, or adjustment, to the requirements of the situation. Darwin's theory of variation has been supplemented by mutationism; and experimentation has shown that selection does not actually result in the production of new types but rather in the segregation of existing types and the preservation of mutant traits having survival value. Environmental selection does not produce adapted types; it preserves them. The Negro, for example, is black because dark mutant types occurring in his ancestral stock have been favored by climatic conditions. Mutations have also affected hair, eye color and skin texture so as to increase his adaptation to heat and sun.

Biological adaptation applies not merely to physical traits but to those reflexes and instincts which constitute an integral part of an animal's adjustment to the major elements of its environment. In man fixed inherited patterns of behavior have been very largely replaced by an unequalled capacity to learn, or to acquire habits suitable to his cultural medium. Adaptation is thus an organizing process, or the gradual development of an integrated scheme of structures and functions suited to a more or less definite mode of life under specific condi-

tions. This process is the outcome of the stimuli and repressions of the environment acting on the potentialities of the organism and producing a greater or less degree of success in the struggle for existence.

The different races of men have obviously undergone more or less environmental selection, notably in adaptation to temperature, moisture, sunlight and altitude. The white, yellow and black stocks have different climatic optima and different ranges of climatic toleration. But such physical adaptations are necessarily more general than specific. They are achieved only over long periods of time, and hence through race mixture and migration tend to become so obscured that broad and true generalizations regarding them are difficult to attain. Moreover man adapts himself to his habitat not so much by mutational differences as by cultural achievements. There is consequently a striking and radical difference in the cultures of peoples living in such widely different habitats as arctic and desert, or wet and torrid. But here again we must note that migration, trade, travel and war diffuse culture traits over areas far distant from those in which they arose. Moreover man succeeds to a degree in adapting the environment to his own purposes. While, therefore, culture must always be adapted to insure survival in a given habitat, the environment is powerless to produce culture traits. Man alone is their architect; and the extent and manner of his utilization of environmental possibilities depends on the state of his cultural advancement. It should not be overlooked, however, that the intelligent adaptation which it is the mission of science to achieve does not free man from nature; rather it signifies an increasing harmony between his mode of life and nature's laws.

Social life and cultural evolution are carried on by means of complicated processes of mutual adaptation among individuals, groups and cultural traits. By education and training the habits of the rising generation are fitted to the prevailing standards of manners and morals. Powerful institutions of social control adjust the differences and rivalries of groups and classes. New culture traits are fitted into the general pattern of life, and revolutionary inventions, such as the capitalist system of industry, ultimately transform every feature of the culture scheme. Cultural evolution is thus a continuous process of mutual adaptation of all parts of an interrelated whole. Society, whether

local group, nation or international community, is a vast collection of elements mutually adapting and readapting themselves to each other so as to maintain themselves in a condition of moving equilibrium. Social adjustments are, therefore, never perfect, because of the conflicts of group interests and values, the extraordinary variability of human nature and the varying hold of social tradition on individuals and classes. Not only do individuals often become badly adjusted to the requirements of their times, but the competitions of groups may break out into open warfare, leading to new bases of mutual toleration and accomodation.

A., *Darwinism and Human Life* (New York 1910); Chatterton-Hill, G., *Heredity and Selection in Sociology* (London 1907); Huntington, Ellsworth, *The Character of Races* (New York 1924); Bristol, L. M., *Social Adaptation* (Cambridge, Mass. 1915).

ADDISON, JOSEPH (1672-1719), poet, dramatist, member of Whig governments and literary apologist therefor. He had a permanent influence on morals and journalism through his periodical essays in those admirable journals of society, the *Tatler*, the *Spectator* and the *Guardian*. He was the first English critic, in the light vein, of both morals and manners, and with Sir Richard Steele created a vehicle for instructive and entertaining comment that served as a model for many similar magazines and substantially influenced our later periodical literature. His method was that of wit and satire; his purpose to correct the affectations and licentiousness of his time. Vice and profligacy were painted in their true colors by Addison, who destroyed the idea that genius and wit had to depend upon indecency. He reconciled virtue and good sense, yet escaped the Puritan gloom. The wit of his social satire was humane and gracious, unmarred by malice, coarseness, the bitter contempt for humanity of Swift or the ironic cynicism of Voltaire. Good nature, good sense and good feeling mark his thought; and his wide range of interest in the daily problems of human life served both his own age and posterity.

He made his themes entertaining and edifying to a popular audience, bringing, as he says,

"philosophy out of closets and colleges to dwell at tea-tables." This is his great contribution: he revealed the power for instruction and reform of what today we call human interest and the feature article. He created characters, used drama and allegory and spiced all with humor set forth in a style miraculous for a sweet clarity. He made literature a part of daily life, thus giving to journalism a new field between the daily news sheet and the controversial pamphlet, and a new technique that avoided equally the sensation mongering of street literature and the classic aloofness of the essay by Bacon or Milton. Addison (with Steele) also first discovered women as readers and discussed their interests, recognizing them as part of the popular audience, though with an unflattering criticism of their empty pursuits. His good sense and humanity, his moral purity and reverence for the sublime in man and nature, set him as a milestone in the progress of social criticism.

ADELUNG, JOHANN CHRISTOPH (1732-1806), German historian, philologist and lexicographer. He was educated at the University of Halle and from 1787 until his death he was chief librarian at Dresden. In his *Versuch einer Geschichte der Kultur des menschlichen Geschlechts* (Leipsic 1782) Adelung brought into use the term *Kulturgeschichte* as a substitute for the old term *Geschichte der Menschheit*. History, for him, is not a record of military exploits or political affairs, but an account of cultural evolution. Only by the increase in enlightenment and in intellectual development can the progress of the times be measured. He was also the first to advance the theory that the highest stages of cultural growth were reached by the most densely populated countries.

Adelung is more important, however, as a philologist and lexicographer. No man before Jakob Grimm did so much for the German language. By means of his monumental *Grammatisches-kritisches Wörterbuch der hochdeutschen Mundart* (5 vols., Leipsic 1774-86) and his *Magazin für die deutsche Sprache* (Leipsic 1782-

84) he contributed greatly toward fixing the standards of the German language. Through his philological work he did much to stimulate German national feeling. In his *Ueber die Geschichte der deutschen Sprache* (Leipsic 1781) and in his *Ueber den deutschen Styl* (Leipsic 1785, 4th ed. Berlin 1800) he insists on preserving the purity of the German language. He maintains that borrowings from foreign languages come only as a result of ignorance of the richness of the original German tongue. Language is both the expression of the national character and the chief factor differentiating one nationality from another. He therefore calls for a more diligent study of the German past. In his *Mithridates oder allgemeine Sprachkunde* (vol. i, Berlin 1806, vols. ii-iv edited and completed by J. S. Vater, Berlin 1809-17) he formulated the idea of an original Aryan language, a hypothesis which became important in the growth of the Aryan race theory in the nineteenth century. Adelung's work became the model for various Slavic scholars like Linde, Jungmann and Dobrowsky; thus he indirectly contributed to the national renaissance of the Slavic nationalities.

In addition to his more scholarly work Adelung was also active as compiler, translator and journalist.

ADJECTIVE LAW. *See* PROCEDURE, LEGAL.

ADJUSTMENT has much in common in meaning and usage with the terms accommodation and adaptation. The word has been employed in several departments of human thought. Aside from common parlance the term is used in the fields of material phenomena, such as mechanics, in biology, in psychology and in the social sciences.

In mechanics adjustment connotes rearrangement of parts to produce better functioning, such as setting the screws of a lathe or setting the springs of some measuring device. In fact the term has been widely used to denote the fixing of precision instruments in order to make more accurate physical measurements. This in turn implies the determination of a standard or norm of measurement in reference to which adjustment is made. In natural science the norm of adjustment is fairly easy to calculate in terms of probabilities of observation and

verifiability through repeated use of exact instruments.

In the biological world the term has had two usages: one rather narrow, exemplified by the cognate word "adjustor" in reference to certain muscle groups, especially the brachiopods, and by the phrase "adjustor neurone" in reference to the central neurone of the reflex arc; in the wider sense the word is used as practically synonymous with adaptation. Thus Herbert Spencer stated in his *Principles of Biology*: "Throughout all phases of Life up to the highest, every advance is the effecting of some better *adjustment* of inner to outer action." In biology, then, the term has been used, first, in reference to the balance between various organs or parts of the organism in their total functioning, and second, in the sense of the relationship of the total organism to its inorganic and plant and animal environment. The former phase is that of morphology and physiology, the latter that of ecology. In the latter sense the whole concept takes on a more dynamic meaning, as in the phrase "the process of adjustment" of the organism to its surrounding world. Nevertheless in the biological world the norm of adjustment is more difficult to determine than in the inorganic world. Perhaps the statistical average offers the best determination of this norm. But even so it is largely relative to conditions in the organism and in the environment.

In psychology the terms accommodation and adaptation were in far more frequent use than adjustment until the rise of a more distinctly objective, mechanical standpoint in studying the behavior of organisms. The word adjustment did appear in the quantitative manuals of laboratory exercises, but again largely in reference to mechanical fixation of instruments for exact measurements of the temporal phases of reaction, especially in experimental work which rested largely on physics, as in the field of vision and audition. So, too, the phrase "observational adjustment" was used in psychology with special reference to the statistical averaging of experimental findings.

The more frequent use of the term in psychology arose out of two recent influences—behaviorism and psychiatry. Watson employs the term in reference to kinesthetic-motor and other processes. In fact he uses the terms "adjustment," "response" and "reaction" almost interchangeably. Adjustments are both "partial," as in blushing, winking, "single habits," etc., and "complete" in the sense of

the consummatory responses of the whole organism in reference to the stimuli. Watson makes clear his usage of the word by reference to the cycle of the organism's responses, from physiological tensions, in the absence of food, for example, to the completion of the activity when the taking of food results in the release of these tensions. The correlation of the concepts of psychiatry, including psychoanalysis, with objective studies in behavior led, in such a field as education, to discussions of the "adjustment" of children to school environments, to parents, to teachers and to other children. On the pathological side there has been considerable employment of terms like "poor school adjustment," "unadjusted school child," "mal-adjusted child." The term has been in frequent use in the last decade among writers in the field of pedagogy. Here again the matter of norm or standard arises, and there is always an implicit if not explicit standard, often vague, of what constitutes normal adjustment. Statistical averages of behavior or more qualitative standards of social valuations have been used as the norms of adjustment.

In sociology, likewise, the term has grown up in two fields: in systematic sociology, where the term is used synonymously with adaptation of the organism to social environment; and in the field of social pathology, in which the word is employed with regard to the relations of the person to his family, community, political state or economic order in reference to some assumed standard or norm. In connection with systematic sociology the term has come into common parlance in the discussions of human ecology, in which emphasis is placed upon the adjustment of the personality to its geographical and social environment. In the latter field the term has been borrowed from clinical psychiatry and psychology in treating social problems of crime, delinquency, poverty and relief, feeble-mindedness and the social implications of divergent personal life.

In anthropology the term "race adjustment" has appeared in treating racial and sub-racial group relations. In political science adjustment has been employed to describe functions and relations of governmental agencies. In economics it has been used in reference to insurance settlements, to wage and hour arrangements between employers and employees and, in loose usage, to supply and demand and price relationships.

ADLER, GEORG (1863-1908), German economist and historian of socialism. He was born in Posen and held professorships in economics at Freiburg i. Br., Basel and Kiel. His youthful interest in socialist ideas, which he later rejected as utopian, led him to write important critical works on the early history of socialism and on Rodbertus and Marx as the founders of scientific socialism. He was a severe critic of Marx but admitted the historical necessity of the socialist movement and its importance in bringing about social reforms which would lead eventually to a type of economic constitutionalism. Adler, in accord with his general social philosophy, was one of the first advocates in Germany of international legislation for the protection of labor. He also made contributions to economic history and was distinguished as a lucid writer and successful teacher.

K. DIEHL

Important works: Rodbertus, *der Begründer des wissenschaftlichen Sozialismus* (Leipsic 1884); *Die Geschichte der ersten sozialpolitischen Arbeiterbewegung in Deutschland* (Breslau 1885); *Die Grundlagen der Karl Marxschen Kritik der bestehenden Volkswirtschaft* (Tübingen 1887); *Die Frage des internationalen Arbeiterschutzes* (Munich 1888); *Geschichte des Sozialismus und Kommunismus* (Leipsic 1899).

ADLER, VIKTOR (1852-1918), founder and leader of the Austrian Social Democratic party. He was born in Prague of well-to-do parents, but while he was a small child his family moved to Vienna, where he remained until his death. He practised medicine and, because of his early interest in the condition of the working classes, was anxious to become a factory inspector, but he did not succeed in securing an appointment from the reactionary government. Under the personal influence of Bebel and Engels he joined the Social Democratic party in 1885. A year later Adler founded a weekly, *Die Gleichheit*. In 1888, largely through his efforts, the hostile moderate and radical factions of the party were brought together at the Hainfeld convention and a united party was formed. In 1889 he founded the *Arbeiterzeitung*, published first as a weekly and converted into a daily in 1895. It

became the official newspaper of the party and today is still one of the leading organs of the Second International. In 1905 Adler was elected to the lower chamber and remained a member until his death. A year later his great struggle for universal suffrage was brought to a successful conclusion. As the leader of the party in 1918 Adler provided the driving force for the creation of a republic of German Austria; as its first foreign minister he declared its willingness in principle to join republican Germany. He was then already fatally ill and died on November 11, one day before the official declaration of the establishment of the Austrian Republic.

Adler has been falsely called an opportunist averse to theory because in the difficult pre-war situation he was constantly driven to mediation and compromise, first between the hostile factions of the party and later between the various nationalist movements of the polyglot empire. However, a thorough study of his tactics proves, and many of his pronouncements confirm, that he constantly sought to orient his tactics in the direction determined by Marxian theory. In addition to being one of the most distinguished Marxist political leaders, Adler wrote several very interesting articles on Marxism, found in the first volume of his collected *Aufsätze, Reden und Briefe* (10 vols., Vienna 1922-28).

ADMINISTRATION, BUSINESS. *See* BUSINESS ADMINISTRATION.

ADMINISTRATION, PUBLIC.

THE BACKGROUND OF MODERN ADMINISTRATION. Public administration is defined by modern writers as the art and science of management applied to the affairs of the state; the term is also used to indicate a branch of the field of political science. In the former sense public administration displays a history coextensive with organized government, and under changing forms marches through the centuries down to the specialized and highly developed systems which are characteristic of modern industrialized states. From some remote period beyond the Egyptian kingdoms, through classical antiquity, the feudal system and the ab-

solute monarchy, into the era of the democratic state, it has been necessary to transact the business of politically organized mankind. These operations collectively are known as public administration.

Fundamental changes have occurred in practice and theory in this long evolution. The general character of administration has always been governed by the physical basis of state organization, by the prevailing level of social and cultural organization, by the development of technology, by theories of the function of the state and by more immediate governmental and political traditions and ideals. In the ancient world and among primitive cultures the circumstances of physical conditions counted heavily. The factor of distance in the administrative system of the Greek and Roman empires on the one hand, on the other the existence of the Nile traversing the administrative areas of the Egyptian kingdom, may serve as obvious illustrations of the point. But geography thrusts its influence straight into the modern administrative world as well, as may be discovered by any who care to dip into the recent literature on regionalism, or by the more technically minded who care to examine the structure of administrative areas in any contemporary government.

In the ancient world it was more nearly true that public administration tended to set the pace in the general improvement of social organization. In the modern world the state no longer pretends to the monopoly which it enjoyed in the ancient; corporations and associations reach far across the boundaries of the state and equal if not exceed the organization of public affairs in extent, complexity and variety. The International Red Cross, international cartels, great national industrial and financial organizations such as the United States Steel Corporation, the Allgemeine Elektrizitäts Gesellschaft, J. P. Morgan and Lloyds fling their organizations over the whole world; and the application of thought to problems of management is more systematic and sustained outside government than within. Governmental organization in the modern world follows rather than leads in the constant improvement of general technique of administration.

How completely the methods of administration have changed is nowhere better illustrated than by reference to some common technologies. For example, take communication, an essential and continuous phase of all

administration, public and private. In the ancient world rulers depended on a horde of slaves who darted hither and thither with messages to officials and tax gatherers. Now the assistant secretary of the British Home Office may be in constant personal communication with any official in the United Kingdom by telephone, and with officials in the outlying parts of the empire by cable or beam radio. Or compare the laborious writing on rolls by a fourteenth century English clerk, so gracefully described by Professor Tout, with the ubiquitous clatter of the modern typewriter or the reproductive capacities of the multigraph or planograph.

But it is not merely the advance in technology culminating in such devices as these which enables modern administration to exist; the invention and improvement of administrative procedures are equally significant. A great gulf separates the accounting of the eleventh century sheriff of Kent who proceeded to Westminster with his accounts and specie, and whose receipt was a notched stick split in two sections, from the elaborate financial and accounting procedures which control the handling of annual sums running into the billions of dollars. How shall we compare the methodology of the census of William the Conqueror, recorded in 1086 in the Domesday Book, with the electrically driven card punch and sorting machines which manipulated the facts about 100,000,000 Americans on the occasion of the thirteenth census? Or how can we assimilate the managerial duties of the mediaeval *échevin* of Saint-Quentin with those of the city manager of Cleveland, Ohio? Technology, in short, has made such strides that the process of administration seems almost to have changed in kind as well as in degree; and it is only upon technological improvements that administration of the intensity and continuous power of the modern state can rest.

Modern administration emerged from the feudal system along with the national state; and its scope has always been profoundly affected by prevailing theories of the function of the state. Mercantilism, with its insistence on public regulation of agriculture and industry and with its control of the fiscal system so devised as to secure a favorable balance of trade, built up an eighteenth century administrative system of considerable magnitude. Mercantilist theory combined with contemporary emphasis upon absolutist concepts of

royal power to construct a powerful organization operating at the discretion of king and ministers. Abuse of power, often abuse of administrative power, weakened the authority of these organizations, in England in the seventeenth, in France in the eighteenth, and in Germany in the nineteenth centuries.

Their ultimate destruction, however, came through the change in political and economic philosophy attendant upon the first century of the industrial revolution. *Laissez-faire* as a guide to statesmen supplanted the interventionist ideas of mercantilism; and administration withered toward an ultimate minimum of keeping peace and order, collecting taxes and maintaining public works and buildings—duties which were often discharged by local rather than by state officials.

Such an administrative inheritance was received by the newly recognized American states in 1789. It fitted admirably the physical and social data of the period. Means of communication were tedious and uncertain; the population was scanty and dispersed; the movement of the population was at a minimum; the factory system was unknown, substantially the whole population being engaged in farming, fishing and simple commercial operations; money was scarce and the average income slender. For such a people a decentralized self-governmental and inexpensive system of administration was essential.

In the United States, as in England, France, Germany and other industrialized states, the industrial revolution which precipitated an era of *laissez-faire* politics eventually led to a new era of state intervention. A new world rapidly emerged in which old ideas led to such abuse that the state was required to step forward once more to the task of regulating the economic life of its people. The factory system created new industrial urban centers; the railroad enormously increased the mobility of persons; the steamboat expedited mass movements of population; modern problems of health were envisaged, as medical and sanitary science made the amazing progress of the last half century; unregulated industrial competition gave rise to the gravest social problems for the working class. In short the modern world with its complex of economic-social-political problems took the stage; and as it faced its problems the state turned largely to its administration for the solution.

Thus have flowered the diverse and ubiqui-

tous administrative systems of the twentieth century. The state has been compelled to inspect and regulate factories, to modify the competitive system of regulation of hours and conditions of work, by fixing minimum wages and by insuring individual and social protection against the hazards of modern life by extensive plans of social insurance. The state elaborately and minutely conditions the operation of public utilities or displaces them by various forms of state enterprise. The state assumes a positive role with regard to public health, destitution, defectives and delinquents. The state recognizes responsibilities, in America on a vast scale, for the education of its citizens. The state and its subdivisions embark on far reaching plans of construction of public works, conservation of natural resources and provision of facilities for recreation and the enjoyment of the arts. Finally the state undertakes to control conduct in many novel ways, whether by restricting freedom of movement and intercourse, as in certain European countries, or by restricting the use of alcoholic beverages, as in the United States, or by combating belief in certain political dogmas.

The administration of the affairs of the state has been deeply affected by various external conditions other than those to which reference has already been made. Political influence has handicapped public administration in most states, perhaps most lamentably in the United States. Here as elsewhere this handicap is gradually declining in importance. Competition with business administration disturbs the stability of personnel in the United States, particularly in the professional and technical service; this factor counts for relatively little in Great Britain or on the continent. There the prestige value of public employment is sufficiently great to be accounted a positive helpful influence in maintaining efficiency and esprit de corps. Everywhere the degree of public confidence in officialdom counts heavily in forming the character of the administrative service.

Administrative methods have been greatly extended and strengthened as the scope of state business has enlarged. The traditional clerk of Anthony Trollope dealt with papers in the seclusion of his office, and much nineteenth century administration was summed up in the activities of the writing assistant. Six of every ten modern civil servants spend their official life away from headquarters in the field service in actual contact with the world of affairs, in-

specting, authorizing, prohibiting, encouraging, ruling and adjudicating. To the modern civil service have been granted powers of initiating new rules of conduct (rule-making power) and powers of determining liability in the first instance, sometimes conclusively (quasi-judicial power). The administration is thus acquiring ranges of influence which trench on the traditional duties of legislatures and courts.

PROCEDURES AND PRINCIPLES. This positive role of the state is responsible for the development and maintenance of the vast administrative structures which now characterize modern governments and which distinguish them so sharply from their predecessors. Their effective management gives rise to the modern problem of administration. But the existence of these organized bodies of permanent professional civil servants sets also significant problems of their control, as well as other problems of their most effective correlation with legislative bodies and courts. In the following paragraphs is presented a brief summary of this subject matter, which in its generalized form is common to the management of any organized group: business, philanthropy, education, the church.

The philosophy and procedures of scientific management, first stated by Frederick W. Taylor, have set up new ideals which government and business are now seeking to approximate. Taylorism is driving Jacksonian democracy into the limbo of outworn creeds in every extensive administrative system in America, and is exerting a deep influence upon European systems as diverse as the French and the Russian. Scientific management insists upon the one best way of performing any operation, the discovery of which is a responsibility of the higher officials, using strictly scientific technique. Scientific management therefore looks toward the elimination of waste, the standardization of processes, the improvement of technique and the most nearly perfect adjustment of the worker to his work. In the industrial world it envisages a constantly increasing productive power; in the governmental world it indicates reduction of taxation or extension of service.

Public administration has been less successful in adopting either the ideals or the methods of scientific management than have the more progressive industrial concerns. Governments are not engaged in mass production of standardized articles, the process in which scientific

management has made its most striking achievements. Many public enterprises are on so limited a scale as to prohibit any significant refinement of technique. The traditions of the public service are often unfavorable to scientific management, and trade union influence is frequently strong in opposition. Motivation among public officials is much less related to profit taking than in industry, and in the public service profits seldom serve as a measure of success. Nor does competition affect public administration to any substantial degree. In spite of these handicaps steady progress has been made in developing definite and well understood procedures, the more important of which are sketched below.

Historically perhaps the first which requires mention is the establishment of permanent tenure and methods of selection intended to secure competent officials and employees. A Prussian code of 1794 recognized permanent employment as a *fait accompli*; English pension legislation of the early nineteenth century made similar assumptions which were confirmed in 1855; in France no legislation has yet declared the principle, which is nevertheless generally recognized; in the United States the Pendleton Act of 1883 finally inaugurated the principle, which has now been extended to protect the bulk of the federal service, some of the states and most of the large cities. A recent decision of the Supreme Court of the United States (*Myers v. United States*, 272 U. S. 52), however, confirms the power of the president to remove any officer of the federal system, and almost nowhere in the United States are there jurisdictional guaranties similar to those which exist in France. Permanence of tenure nevertheless has come to be a distinguishing characteristic of the modern civil service.

The expectation of permanent service made inevitable greater care in selection. Progressive refinement has been made in formalized examinations, which have thus developed from simple pass examinations through free answer competitive tests to the standardized short answer tests and psychological tests of the present day. English examinations for the higher branches of the service have always been academic in character, intended to discover the finest brain power in each generation of university men, without specific reference to their knowledge of administration.

Recent developments in the United States are rapidly substituting tests of aptitudes, skills

and general intelligence for tests of special knowledge. For the higher branches of the Prussian and German imperial administration a university examination gave access to a prolonged period of special training in law and administration which was concluded by a state examination. In Anglo-Saxon countries current disquietude as to the validity of the examination process is paralleled by persistent and significant attempts to improve the selective power of tests. After a protracted controversy there is, however, general agreement among responsible administrators that some type of examination is both feasible and essential.

As the variety, extent and complexity of public administration developed, and its costs mounted, the need for coordination and central direction became urgent. The Conseil d'Etat (*q.v.*) in France was one of the earliest modern inventions to meet this need. During the history of the German Empire the Bundesrat (*q.v.*) performed functions as the coordinating center of imperial administration. In Great Britain the Treasury has long exerted powers of coordination and control over the whole administrative system.

These powers include the formulation of the budget and the revision of departmental estimates; the specific approval of all departures from the financial votes of Parliament and approval of all new or increased expenditures; general control of such expenditures as those for supplies, printing, public buildings and quarters; and, since the war, specific control of establishments, fixing the number, salary and promotion prospects of employees in all departments. The British Treasury has now become one of the most powerful agencies of general management to be found in any system of public administration; its rationale may be read in the brilliant report of the Haldane Committee on the Machinery of Government (Cd. 9230, 1918).

Similar institutions have recently been established in the United States. Among these may be cited the Illinois Department of Finance (1917), the United States Bureau of the Budget (1921), the Massachusetts Commission on Administration and Finance (1923) and the executive department of the state of New York (1926). These agencies are primarily fiscal in character, exerting a general control over administration through fiscal mechanisms. With variations in emphasis they deal with budget making, current control of expenditures, cen-

tralized purchasing, supervision of printing and, to a less degree, control of personnel.

They are in fact a civil general staff, deriving their real authority from the chief executive and operating to make effective his constitutional position as general manager of public business. In some American quarters fears have been expressed lest so powerful an agency should be abused by politically elected chief executives. The danger exists here and there. In any case those who believe in the democratic faith must place confidence in the beneficial effects of public education, gradually developing higher standards of public morality; they will be profoundly reenforced by the very nature of the modern administrative process, which constantly becomes more technical and more pregnant with social good or ill.

In such administrative systems as that of Fascist Italy, standards do not depend on popular vote, and this problem does not arise. Fascist administrative organization in fact stands at the opposite pole from the American. The contrast between the underlying principles of the two systems brings out the types of organization which are characteristic of the modern world. On the one hand are centralized systems in which administrative authority is concentrated in the hands of national officials, in whom is vested the responsibility for all administrative action, central or local, who appoint, supervise and at will remove local agents to execute orders issuing from above. Richelieu developed this system into full vigor, Napoleon renewed it after the revolution, and with variations it has conquered the Latin world. On the other hand are decentralized systems, inherent in the structure of federal states and characteristic of Anglo-Saxon civilization, in which local autonomy prevails over the demands of central control, yielding in the face of modern economic problems but retaining a powerful vitality well displayed in the home rule movement for cities in the American commonwealths. These contrasting types are more than diverse solutions of administrative problems, for they are based on dominant and settled points of view involving the whole relation of citizen to government, and are affected by the role each state plays on the stage of international affairs. Strong centralized administration is often in part the outcome of international fear.

The centralized type of administration is related to the bureaucratic (i.e. the professional),

the decentralized type to the self-governmental (i.e. the amateur). Fascist Italy has eliminated the amateur from her administrative system in favor of a politico-professional bureaucracy; the United States, in spite of the technical nature of many aspects of administration, is still powerfully influenced by preference for amateur self-governmental forms. It is estimated that over 750,000 public officials are still elected by the American voters in local, state and national elections. This is a reflection of the rural character of vast areas of the United States as well as of a special theory of democracy; in the urban regions popular election and the theory of rotation in office are slowly disappearing from the administrative hierarchy.

Historically the British administrative system has been decentralized and self-governmental. Throughout most of the nineteenth century the counties and boroughs performed services of local administration without intervention from Whitehall, although considerable responsibility for the management of poor relief had been transferred to government officials in 1834. The country gentry, in the guise of the justices of the peace, controlled rural administration until the end of the century; in the boroughs the modern system of representative councils and administrative committees was introduced in 1835 although with a limited franchise. The justices of the peace still share responsibility for police with the elected borough and county councils; but the process of central supervision and direction has gone far to create a national minimum standard of efficiency. In Great Britain the tendency is toward both centralization and professional administration.

The administrative system of the modern state is in fact tending to conform to certain general principles of organization, the effectiveness of which is being tested in business and military organization as well as civil administration. There is a strong tendency toward unity in the whole system, combined with the intent to concentrate responsibility in a single official. This has always been characteristic of the continental centralized systems, and the principle is now rapidly being recognized by American cities (strong mayor or city manager form), by the reorganized American commonwealths (Illinois, New York) and by the federal government through the notable development of the administrative powers of the president of the United States. The administrative organization of English boroughs is now the chief stronghold

of the contrary principle; there is some evidence that even here the need for unity is being felt, especially as new duties are heaped upon local government by act of Parliament.

Modern administration also gives wide expression to the principle of specialization. Rural systems remain an exception in part, but here also technical operations, such as highway construction and public sanitation, are deeply influenced by specialization. This principle involves not merely the progressive establishment of administrative units for different types of work organized by functions, but also the employment of experts of many kinds to perform the work. In large municipalities and in most national systems administration has become the work of the expert to a measure infrequently realized. The whole process of government needs to be reconsidered from the point of view of the expert, to determine the most effective means of utilization of his techniques.

This consideration raises the problem of the proper function of different types of administrative officials. It is obvious that the duties of a chief executive are not those of an accounting officer, and that the responsibilities of a junior clerk are different from those of a bureau chief. The most reasoned allocation of function is perhaps to be found in the British system. There a sharp distinction is drawn between the duties of the political and those of the permanent head of the department. The former is primarily concerned with the external contacts of the ministry, relations with ministries, with the cabinet, with Parliament and its committees, with the press, parties and the public. He is a buffer between the political and the administrative worlds; but also he has to keep his staff out of a rut and alert to the most advanced administrative methods.

The permanent head of the ministry is the official responsible for the organization, direction, supervision and management of the staff, acting always in harmony with the policy of the cabinet and of the minister. He also has to advise the minister on all matters of concern to the department, and often exerts the most powerful influence on the actual conduct of affairs. The contact between the political and permanent head is in the English system the effective contact between amateur and professional, between politician and expert.

A bureau chief has specialized and often highly technical duties to perform. The bureau (i.e. the primary subdivision of department or

ministry) is the fundamental unit of administrative organization, homogeneous, compact and specialized. Two types can readily be distinguished: those performing duties essential to the maintenance of the organization as organization (purchasing bureau, recruiting agency, disbursing officer) and those performing the operations for which the organization exists (detective bureau in a police department, income tax unit in treasury department). The former are termed institutional, the latter functional. In either case the bureau chief tends to be a highly specialized officer, intimately acquainted with the duties of his bureau. He is not concerned with policy further than to call to the attention of his superiors the need for legislation. His contacts are administrative and he looks within rather than without the administrative machine. In Great Britain special recruiting of officers of general administration (assistant secretaries, bureau chiefs, etc.) is deeply deplored by the professional-technical group, who are generally barred from this range of duties.

In lower levels the specialist is the dominant figure. American theory and practise tend to recruit the specialist already formed; English to recruit potential ability which (excepting the professions) is then trained within the service.

Simple administrative organisms which are adequate for rural or undeveloped communities do not present a difficult problem of coordination, but the complicated structures necessary to carry forward the activities of great cities or industrial states require elaborate machinery of coordination in order to prevent duplication, lost effort and internal friction. In the United States the most elaborate machinery developed for this purpose is found in the Bureau of the Budget, in the person of the chief coordinator and in a considerable number of coordinating committees. These committees, representative of the departments and independent establishments, lay down rules and understandings which govern administrative operations. The will to coordinate in the first instance was imposed by the director of the Bureau of the Budget; an unfortunate tradition of departmental autonomy was formerly unfavorable to voluntary cooperation.

In Great Britain coordination is secured chiefly through the oversight of the Treasury, partly by the operation of the Whitley Council for the civil service and partly by interdepartmental committees. The general extension of

the institutional services (purchasing, provision of quarters, recruiting, etc.) has also operated in the same direction.

Modern administration proceeds in fact on the basis of very highly specialized operations. Management has itself become a profession, touching all the sciences from chemistry and mechanics to psychology and medicine. It is employing lawyers and doctors, accountants and artists. Most of the professions play their role within public administration, and many occupations become highly specialized. The specialization is not merely in a set of procedures, but is even more a specialization in laws, rules and regulations, judicial decisions and customary practises which guide the official when he applies public policy to the particular case. Years of study and experience alone can form such a specialist.

A professional status has long been accorded responsible public administrators in European countries, and is eagerly sought by many groups intermediate in the official hierarchy. Such organizations as the Institute of Public Administration in Great Britain institutionalize this status. In the lower ranks of the public service, however, the tendency is rather toward the formation of trade unions, with normal trade union aspirations.

The trade union movement in the public service is an evolution substantially of the twentieth century, with roots in the postal service reaching down into the last decades of the nineteenth century. In Soviet Russia "civil servants" are a part of the general clerical trade union; elsewhere the public service is separately organized, with varying degrees of affiliation with the general labor movement. The fundamental issue which this novel situation presents concerns the part which organized masses of civil servants are destined to play in the administrative systems of the future. Syndicalist theory assigns them a dominant role, expecting them to maintain the *esprit de corps* and inventive capacity of the future by endowing them with autonomous responsibility for the conduct of the public services. The Joint Council for the Administrative and Legal Services of the British government already forecasts a type of employee cooperation which may become highly significant.

These councils, established both for the service as a whole and by departments, comprise equal numbers representing the official side and the staff side. They are empowered to

reach agreements on most phases of personnel management and have cooperated fruitfully in such matters as the reorganization of the service, reduction of expenditures, fixing the basis of pay, operating the promotion system and making provision for the further education of civil servants. Although harassed by internal dissension, their achievements are of first rate importance.

The maintenance of efficiency is a concern of primary importance to those officials responsible for the operation of the administrative machine. They must restrict entrance to the public service to candidates whose moral and intellectual fitness is assured, and watch every aspect of the whole employment situation to insure that their full potential capacity is developed and applied to the work of the state. The first task is usually vested in the hands of a civil service commission; the second is vested primarily in the higher officers of the several departments. Progressive leaders in employment policies in government and business agree that efficiency can only be secured by bringing into play every means to develop *esprit de corps* and morale.

Morale is both an index of a sound employment situation and a positive means of building an efficient organization. It reflects a social psychological situation, a state of mind in which men and women voluntarily seek to develop and apply their full powers to the task upon which they are engaged, by reason of the intellectual or moral satisfaction which they derive from their own self-realization, their achievements in their chosen field and their pride in the service.

In the absence of systematic and thoughtful attention to the *esprit de corps* of the public service, conditions develop which make it impossible for the state to capitalize the energy, inventive capacity and driving power which await the magic touch to bring them to life. A complex employment situation must be based, if efficiency is to be secured, on justice in the conditions of employment, on recognition for superior employees, on stimulation of leadership and personal and institutional loyalties, on agreeable social contacts and on effective personal adjustment to the job.

The scientific ascertainment of the means by which the necessary psychological environment can be built is one of the main tasks of research in the field of public administration and will call for the united efforts of psychologists,

psychiatrists, engineers, political scientists and sociologists. The actual achievement of an effective psychological environment need not wait for the discovery of its scientific foundations, for already skilful administrators are applying the art of administration to secure first class results.

Ultimately much more will be known as to the relative advantages of various psychological types for given categories of employment. By way of illustration, such a general classification as introversion-extraversion may serve as a preliminary basis for employment preference, the extraverts being directed into posts involving contacts with the public, the introverts being absorbed in office work. Standards of emotional stability are essential for the effective selection of policemen; and tests of honesty are already at hand to aid in protecting the integrity of public offices. Standards of intellectual ability need to be developed, so that the minimum necessary intelligence may be assumed, and so that the intellectually gifted may be quickly inducted into responsible positions, while the intellectually mediocre may be restricted to routine operations. The progressive refinement of these psychological bases of differentiation and their application in public offices are fundamental to high morale and efficient service.

THE CONTROL OF ADMINISTRATION. These broad considerations are fundamental to modern public administration. Specific consideration of administrative technique may be found in related articles. One important set of considerations remains, however, to be dealt with: the relations of public administration to the legislature and to the courts. These connections are partly formalized in constitutions and statutes and common law; they are partly customary and traditional, fluctuating from time to time as personalities shift and change.

Considering first the relations between legislatures (Congress and Parliament, state and provincial legislatures, city councils) and the administration, we may note that constitutionally the legislature is placed in a superior position as the ultimate representative of the sovereign people (except in such systems as now prevail in Spain, Italy and many colonial governments). In the modern democratic state, after a long constitutional struggle, the executive has been constitutionally subordinated; the administration now looks to the legislature for its organization and structure, its funds, its

tasks, often its methods; and it accounts to the legislature for its acts and expenditures. Legislatures have invented many devices to insure that this responsibility shall be a real one; yet one of the paradoxes of modern administration consists precisely in that the more the legislature strains to control administration, the less it succeeds. Fascist Italy has foregone the attempt; liberal England finds the task too great for systematic performance; but in France the parliamentary commissions perform their duties with such aggressiveness that the stability of the government is weakened.

It is clear that the task of legislative control has to be simplified and generalized to the utmost in order to make it tolerable. Administration has come to such a varied, extensive and technical state that no body of men deriving from a political environment, rapidly changing in personnel, meeting intermittently and absorbed with pressing issues of public policy, can expect to act effectively as a board of directors. Control to secure efficiency and economy is probably not at all an appropriate function of the legislature, but should derive from the internal organization of the administration itself.

The legislature does, however, have a legitimate function to perform *vis-à-vis* the administration. It may properly undertake to require the administration to operate within the limits of general legislative policy, to inquire into the propriety of expenditures and criticize the whole range of administrative operations, to insure that the administrative control is operating to secure efficiency and to inform itself thoroughly of the conditions of administration in view of remedial legislation.

There is much evidence that the constitutional role of the administration is in process of reconstruction. Legislatures are now faced with an almost superhuman task of dealing with a range of social problems, the intelligent solution of which depends less upon broad intuitions than upon masses of data from which conclusions emerge only by scientific treatment. In their solution the advice of administration is often the most significant that legislatures can call upon. Hence it results that legislative texts are frequently written by anonymous officials, sponsored by the executive and agreed to by the legislature. The latter become adjudicators of social policy rather than initiators.

The parliamentary system institutionalizes this process in large part, while in American

municipal government the tendency of city managers to suggest, formulate and guide the decisions of city councils parallels the movement in national circles elsewhere.

On a broader scale it has to be recognized in representative governments that administration, like legislation, must proceed on a basis of consent. The public enters as an influential party. It may strengthen or weaken administration from the jury box or at the polls (election of sheriff, prosecuting attorney). The special public concerned with particular phases of administration often secures a more definite recognition by assignment of its representatives to advisory boards or to responsible commissions (workmen's compensation commissions). Croly has pointed out that the most doubtful and difficult question connected with the administrative organization of a progressive democracy concerns its ability to obtain and keep public confidence. As administration extends its compass and refines its technique, the difficulty increases; but a healthy recognition of the underlying objectives of administration in terms of service goes far to maintain a proper balance.

The administration and the courts are in constant contact with each other, thus giving rise primarily to questions of administrative law. But considerations of efficient conduct of public affairs are also frequently engaged. Historically local courts have carried the brunt of local administration, as in Great Britain until the reform of local government in 1888 and 1894; even today the courts share responsibility for the British police system. In the United States the county courts of the southern states perpetuate this English inheritance.

Broadly speaking, however, the judicial system now stands as a controlling agency, holding the entire administrative system within the bounds of law and offering redress to those whose rights may have been infringed by official action. In Anglo-Saxon jurisdictions the ordinary courts perform this function; on the continent a separate series of administrative courts prevail.

The development of the regulating functions of administration, as well as the determination of the limits of official discretion, is governed by the views of courts concerning the proper limits of administrative action. In the United States diverse tendencies are at work, resulting on the whole in a recession of judicial interposition. This has developed in part by statu-

tory extension of official power, as in the enforcement provisions of the Eighteenth Amendment, in part by more tolerant attitudes on the part of the courts. In each case there is a better appreciation of the peculiar qualifications of administrative officials to deal with the diverse and delicate situations which modern government attempts to regulate. Courts are specialists in law and in Anglo-Saxon jurisdictions rely on precedent; officials are specialists in social situations and look toward the future rather than the past.

The courts retain ultimate power of control in most circumstances; and in cases of excess of power, failure to observe procedural requirements or abuse of power, will regularly intervene to protect individual right. A very significant tendency of the twentieth century is, however, the assumption of quasi-judicial powers by administrative commissions (utility commissions, compensation commissions, minimum wage commissions, valuation boards, etc.). Modern administration is based more and more on general legislative texts which presuppose that officials will define and redefine their content; it is thus freed from the necessity of observing the detailed requirements which were formerly imposed by statute, and the occasion for judicial interference has thereby been lessened.

TRENDS. The underlying trends of modern administration are not always easy to segregate and define. Some, however, seem reasonably clear. There is yet no conclusion to the growth of administrative functions, although there has been a recession from the abnormal situation induced by the war and a general slowing down of the expansion of function by reason of financial stringency. The intensity of administration, a factor unrelated to extent, increases year by year and may be expected to develop gradually for an indefinite period. The scope and intensity of public administration are both functions of a prevailing socialized philosophy of government which seems to be characteristic of such widely diversified systems as the American and Russian, the British and the Italian.

As these trends move on from decade to decade, they emphasize the decline of the amateur and the dominance of the expert. The amateur administrator long ago lost his hold on the national services and is disappearing in the larger local services as well. The reform of English local government in the last decade of

the nineteenth century, the establishment of the American city manager plan in the twentieth, are indications of a continuing process by which specialization, permanence and professionalism are conquering the public service. From another point of view this marks the transition from self-governmental institutions to bureaucracy.

The center of gravity of modern administration is moving from periphery to center. This shift is rendered feasible by technological improvements in communication and transportation, and is rendered wise by virtue of savings in outlay and expenditure, by improvement in many specialized forms of public service (institutional care of insane, defectives and delinquents) and by greater ease in supervision and control. Certain phases of administration remain localized and by their nature would seem likely to continue so; for instance, family care, mothers' pensions, recreation in large part, baths; protection of person and property. Here, however, as elsewhere, the case for central agencies giving thought to administration seems unimpeachable. Lord Haldane's brilliant suggestion for a Minister of Research and Information remains to be made effective, but the Privy Council Committee on Research and in America such semi-official agencies as the National Research Council and the Social Science Research Council are distinct indications of possible developments.

In America, especially, there has emerged in recent years a pronounced tendency to enhance the administrative power of chief executives, including the president, governors, mayors and managers. Two types of executives are competing for supremacy, the political and the professional, and it is much too early to indicate which will prevail. Whichever ultimately predominates, it is safe to conclude that the integrity of a professionalized service will be assured.

Following the war came a distinct tendency to modify the autocratic management of personal relations within the public service. The democratization of business had its repercussions in government, most notably in Russia, but also in a significant manner in Great Britain. Reaction soon overtook the hopeful surge of feeling which succeeded the armistice, and it is unlikely that democratic or radical theory will introduce any marked innovations in the practises of personnel management.

There is, nevertheless, a decided tendency in

continental systems to grant a jurisdictional protection to rights of employment, which are less extensive in Great Britain and uncommon in the United States. This takes the form of an administrative appeal from official decisions by employees whose interests have been injured. In America public employees are in this respect more nearly on the footing of industrial employees.

ADMINISTRATIVE AREAS. Administrative activity is as old as government itself. Greek, Roman and mediaeval analogies offer instructive comparisons to the modern administrator. The emergence of a separate function or machinery of administration, however, is a product very largely of the nineteenth century. The new tasks thrust upon or assumed by government as a result of the new conceptions and broader requirements of communication, education, public health and public welfare hastened the process of political reorganization and functional differentiation which marked the progress of the industrial revolution. A comparison of the effects of this process upon administrative areas and their proliferation in the larger states will indicate its general outlines.

In the United States the federal government has developed its relatively few administrative districts—treasury, judicial, customs, federal reserve, etc.—without interfering with state boundaries. The states, which have complete constitutional control over their own territory, have, on the other hand, elaborated a great variety and complexity of areas. The traditional

subdivisions of the state are the county and, for local government, the town (New England) or township (south, middle and west). There are over 3000 counties in the country, varying greatly in size (25 to 30,000 square miles) and population (65 to over 3,000,000). "The typical county may be said to have an area of 600 square miles and 20,000 population" (Dodd, p. 348).

The disparity between the traditional county boundaries and a realistic remapping of administration in accord with the shifting of population and rapid urbanization which has taken place all over the country has led to two expedients: the setting up of new areas for new functions, and the sanction of county unions for special and limited purposes.

Practically every state has for its own purposes types of administrative areas—fiscal, electoral, judicial, park, public health, police, road, education, conservation, etc.—which overlap the county division or disregard it altogether. In addition to these are the many local areas and metropolitan districts which have grown up during the last century. Only a few states, on the other hand, have, hesitatingly enough, allowed counties to cooperate, under home rule or county manager charters or by special legislation, for joint administration of such services as roads and hospitals. The reorganization of state administrative areas on a logical plan has received very much less support in practise than it has in project (see Governor Smith's Messages, Albany, New York, Jan. 5, 1927; Jan. 4, 1928).

Local administrative areas have gone through the same process of dissection at the hands of the states. Not only have they been chopped up into various unrelated and often conflicting areas for special purposes—for example, schools, roads, parks, water, drainage—but the rapid growth of cities has added confusion to the existing puzzle map. Various plans have been tried to overcome the anomalies of anachronistic political boundaries: the merging of city-county areas and functions, the erection of an expanding city into an independent county, the limited control by the city over adjacent territory, the federation of cities for special purposes, the creation of metropolitan districts, the consolidation of urban areas with local autonomy for limited purposes, or the complete unification of such areas (Dodd, Maxey). Meanwhile state boundaries have offered similar obstacles to efficient administration of newer

regional activities such as flood control or power development. Numerous interstate "compacts" have been sanctioned by Congress, the most notable of which is that creating the Port of New York Authority (Frankfurter).

The great acts reforming local government in England began with the *Poor Law Amendment Act* and the *Municipal Corporations Act* of 1835. For a half century afterwards the same process as in America of creating *ad hoc* areas for special purposes resulted in the same "chaos of areas, of authorities and of rates." Consolidation of areas began with the *Public Health Act* of 1875 and has continued to the present; the *Act* of 1929 removed the last serious anomaly by the complete transfer of poor law functions from some 640 old poor law unions to the 142 counties and county boroughs.

The present administrative areas of England are as follows: administrative counties, 62; county boroughs (large cities), 82; metropolitan boroughs (old crown charters), 253; urban districts, 782; rural districts, 602; parishes, 14,300. Many joint authorities have been set up under permissive acts, such as those for roads, town planning and electricity supply. Central control is for the most part consolidated in the Ministry of Health, thereby insuring responsibility to Parliament. This ministry succeeded the Poor Law Commissioners (established in 1834), the Poor Law Board (1847), the Board of Health (1848) and the Local Government Board (1871).

In contrast to the American, and in large measure to the English, theory of local administration, France, Germany, Italy and Japan have highly centralized systems of national control. The details of the hierarchy of districts vary in the different countries. Germany has 18 states, each divided into separate groups of districts, Prussia, for example, being composed of provinces, administrative districts, counties (urban and rural), cities, rural communes and manors. France has 90 departments, 279 arrondissements, 3019 cantons, 37,981 communes (of which over 22,000 have a population of less than 500). In these and other centralized countries the focussing of control at the political center follows naturally from the fact that it is the center of gravity of the administrative system; in England and the United States central control has been elaborated at the expense, and often in the face, of the persisting tenacity of local loyalties.

The growth in the range of international

administration has already created what may be termed international administrative areas. Tangier, the sanitary councils, the river commissions, etc., are pre-war examples, while the direct territorial responsibilities of the League of Nations (Danzig and the Saar Valley), its work in Greece (exchange of populations), in Austria and Hungary (finance), in Poland (health) and the mandates are indications of a great future expansion in this field (Sayre).

The real problems arising from the increase in administrative areas result from the "lag" in the changing of boundaries to meet the facts of human migration and shifts in economic activity. Differences in size, population and taxable capacity between different areas subject to similar responsibility create intolerable situations which are still further accentuated by changes in wealth and population and by differences in the political institutions of different countries. Moreover, as administration is a function of locality, its form and technique must change with the locality. As locality is a function of space, so is space a function of time; with the profound changes in the speed and ease of communication in the past century, the whole problem of administration has been modified and the area of effective control broadened.

Various plans for reorganization have been suggested. Their variety and ingenuity may be indicated by a reference to the Webbs' scheme for the "cellular" organization of England, "county boroughism" (Finer, "Neue Entwicklungstendenzen"), the "regionalist" movement in France (Brun, Hennessy), and the regional planning and power projects in the United States.

Others have suggested more fundamental reform by striking at the root of the separation of economic and political interests. The Soviet and Fascist states, the German Economic Council (Finer, *Representative Government and a Parliament of Industry*), the guild socialist and other programs (Cole and Laski) are protests of this sort. A functional organization of administration appears to offer great difficulties, although its benefits would be real and are perhaps essential to any final solution of the problem of administrative areas. Meanwhile it is becoming evident in practise that with the increasing mobility of man and his products the area of administration must enlarge. In the words of the Webbs, there must be "aggregation to secure segregation."

ADMINISTRATIVE LAW.

Administrative Law on the Continent of Europe. The central idea of administrative law in French and German jurisprudence is the differentiation of civil and criminal justice from other functions of government. For the adjudication of controversies between private persons and for the punishment of crimes there exist courts which are surrounded by constitutional guaranties of independence; but the executive power is not, in principle, subject to their jurisdiction. Inevitably, however, the

exercise of governmental powers in matters of police, revenue and public services will, by reason of the silence or the ambiguity of statutory texts or by reason of disputed facts, give rise to controversies; and unless private parties are to be subjected to an unregulated official discretion, there must be devised orderly processes, as part of the executive power, for the determination of these controversies, and these in their turn will produce principles analogous to those administered or evolved by the ordinary courts.

This body of law, controlling the exercise of governmental power outside of traditional civil and criminal justice, is designated as administrative law. It covers both regulative legislation and its interpretation, and the inherent principles of official power. The exclusion of the jurisdiction of the ordinary courts leads to a demand for a substitute; and in France and many other continental states special administrative courts have been established. The development of a theory of administrative law is greatly stimulated by a distinct organ of jurisprudence and by the necessity of marking off the jurisdiction of administrative from that of ordinary tribunals. Administrative law has thus become on the continent of Europe a major department of legal science, and has accordingly a status equal to that of civil and criminal law.

Administrative and Judicial Powers in the Anglo-American System. Under the common law of England, received in America, the jurisdiction of the regular courts over controversies involving the validity of official acts, with power to grant relief against organs of the administration, was never lost. Moreover, where legislation had to operate through official powers over individuals of a compulsory or determinative nature, such powers were apt to be vested in courts (in England locally in the justices of the peace) and not in administrative officers. The old common law executive officer, the sheriff, was a ministerial officer of the king's court. England and the American state governments lacked the bureaucratic organization characteristic of the continental monarchical systems as the latter developed during the seventeenth and eighteenth centuries. It is true that in America the organization of local governments separated administrative from judicial functions, and the important power to grant licenses for the sale of intoxicating liquors, which was in England vested in the

justices of the peace, was in most American states exercised by local administrative authorities; and questions in connection with this licensing power compelled the courts to consider the problem of administrative discretion. But administrative orders were not a conspicuous part of the machinery of government, and on the whole administrative law, as we know it now, until the later part of the nineteenth century remained undeveloped, and the term meant nothing to the legal profession. Among jurists there was a tendency to regard it as something foreign to the common law, and Professor A. V. Dicey in his *Introduction to the Study of the Law of the Constitution* (8th ed. London 1915) contrasted the *droit administratif* of France with the "rule of law" in England. The great treatises of the German Professor Gneist on English administrative law apparently received little, if any, attention in England. In America there were well known treatises on the law of officers, the law of municipal corporations and the law of extraordinary legal remedies; but to the present day the term "administrative law" is not to be found in legal digests and is uncommon in judicial decisions.

The Rise of American Administrative Law. As a subject of instruction administrative law obtained a status in university departments of government or political science before it gained a foothold in law schools. Political science teachers emphasized problems of organization (Goodnow, *Comparative Administrative Law*), and the more purely legal aspects of powers and remedies did not become dominant until professional law schools gave the subject a place in the curriculum, which was done only very slowly. Even today it does not occupy the same position as constitutional law. The scientific study of the subject received a new stimulus when the Commonwealth Fund in New York placed it among the research topics to be systematically pursued and subsidized.

In America the awakening of the legal profession to problems of administrative law is associated with the regulation of public utilities, operating through commissions vested with power to issue orders. It was only after the beginning of the present century that this branch of the law was really developed. In the sixties of the nineteenth century a similar order-issuing power had been given to the Metropolitan Board of Health of the county of New York, and its constitutionality, questioned by

lawyers, had been sustained by the courts. The novelty was that a power such as traditionally under the common law system had belonged only to courts of justice was to be exercised administratively by organs of the government not hedged in by the old established checks of judicial processes, i.e. not proceeding "according to the course of the common law." Was this "due process"? The familiar licensing (as opposed to order-issuing or directing) power had presented no similar problem, for according to its nature it tended to be exercised in a routine fashion, and on the whole the interests subject to it found it easily possible to accommodate themselves to its exercise. An administrative order according to its nature is not quite a routine matter; it places itself in opposition to the independent conduct of business; and hence the authority issuing it tends to assume the character of a tribunal and appears to represent a method of law competing with the common law.

As an instrument of legislative policy this method of controlling private interests became conspicuous through the Interstate Commerce Act of 1887. This act operated with terms ("unreasonable," etc.) practically unenforceable without administrative determinations prior to judicial enforcement, and the making of these determinations was entrusted to the Interstate Commerce Commission, an "independent agency in the executive branch of the government" (to use a term more recently introduced into the language of Congress), i.e. not a court of justice but a body whose members were made removable by the president. While the next act of congressional economic legislation, the Sherman Anti-Trust Act of 1890, was a purely penal measure without administrative determinations, Congress, in 1914, by the Federal Trade Commission and the Clayton Acts, and by the Shipping Board Act of 1916, again utilized administrative commissions; and although in 1920 the Packers Act entrusted analogous functions to the secretary of agriculture, the commission vested with determinative powers had become established as an important organ of law administration. The copying of the model of the Interstate Commerce Act in the public utility laws of the states made the method familiar to the entire American legal profession, and administrative law became a recognized branch of the legal system.

The state public utility laws operate through licenses and certificates as well as through orders; and important licensing powers (new

construction, security issues, etc.) were given to the Interstate Commerce Commission in 1920. License or permit requirements were also the traditional method of the legislative regulation of such classes of business as banking, insurance, the liquor traffic, etc. As before stated, the tendency of this form of power to become a routine function had prevented it from becoming a nucleus for the growth of administrative law. Under the Transportation Act of 1920, however, the requirement of notice and hearing as a condition precedent to the issuing of permits promises to invest this type of function likewise with a quasi-judicial character, and to raise in connection with its exercise important questions involving private right, administrative power and judicial control.

Sources and Problems of Administrative Law.

If we describe administrative law as the law of official power and of its subjection to judicial control, we also indicate its two principal phases and aspects. On the one hand the law is concerned with statutory provisions and their construction; on the other hand, with common law principles of remedial law (official liability, extraordinary legal remedies, equitable jurisdiction). But common law also enters into statutory construction, and legislation is controlled by the constitutional principle of due process to which the exercise of power over private rights must conform. It is neither necessary nor profitable to determine how much of administrative law rests on legislative, and how much on judicial, action.

The main problems of administrative law relate to the nature and operation of official powers (permits and orders, ministerial and discretionary, scope of discretion and legitimacy of underlying considerations), the formal and procedural conditions for the exercise of powers, official and communal liability, the specific remedies for the judicial control of administrative action (legal, equitable and statutory), jurisdictional limitations of powers and the question of administrative finality.

The constitutional problems of administrative law relate to the delegability of legislative power, due process in administrative power and due process as involving subjection of administrative power to judicial control. Where the course of administration is in accordance with traditional methods, it is generally assumed that it is not contrary to constitutional limitations or requirements (summary powers,

finality of discretion, absence of common law remedies such as the non-suability of the sovereign). On the other hand common law principles generally work out in such a way that fundamental requirements of justice are respected and operative. Thus if the administrative process in itself falls short of what due process may seem to demand, the application of common law remedies (mandamus, official liability, etc.) by way of correcting the administrative process may supply the defect.

The judicial development of administrative law proceeds mainly through a gradual liberalization of the two remedies respectively applicable to permits and orders, namely mandamus and certiorari; but the courts cannot remedy every defect of the common law, and particularly the harsh operation of official liability cannot be relieved without corresponding hardship to private rights. With regard to this last matter adequate relief may depend upon the legislative substitution of the corporate liability of municipal or state government. The legislature may also do much in the way of simplifying the common law system of remedies, which is perhaps unduly encumbered with technicality, and it may give added protection to private right by throwing safeguards around the administrative process itself, both by circumscribing the substance of discretion and by prescribing appropriate forms for its exercise. In these respects the development of regulative legislation has incidentally brought in its wake also a development of administrative law.

The Law of Administrative Practise. So far as the statutes are silent and are not aided by well-established rules of construction or of the common law, administrative authorities must themselves determine in the first instance how they will exercise their powers; and the practises which they observe will control private interests except as they may be checked or overruled by successful appeal to the courts. Administrative practise will thus always have an important place in the actual functioning of government. Voluntary and long continued administrative practise has many of the characteristics of law and, under favorable conditions, inherent guaranties of fairness may approach those which are generally associated with courts of justice. We are inclined to accord to the courts a law creating monopoly, and administrative law is to us primarily judicial law controlling the administration. The term

might, however, also be applied to a body of principles produced by the administration; and with the growth of administrative tribunals, and particularly of a practise of publishing reports of administrative decisions and of abiding by precedents, there is every reason to suppose that such a body of commission or departmental administrative law will gradually establish itself.

The quality of such administrative law as the administration itself may produce will greatly depend upon the character of its organization. In the modern constitutional state this organization is in the main fixed by written law, and the principles which guide this organizing legislation are also legitimately designated as administrative law; French and German and American writings on the subject are perhaps primarily given to the discussion of organization. There is now, however, a tendency to differentiate the study of organization and the study of powers. The former, involving public administration, aims to discover the conditions reconciling efficiency and economy with avoidance of the drawbacks of bureaucracy. The latter, involving the principles making for the protection of right and justice, is viewed as the more strictly legal discipline of administrative law, using the narrower sense of the term.

Law Enforcement. There remains a further important aspect of administration which is concerned with law enforcement. The process of enforcement is to such an extent dominated by the courts, and also so closely associated with criminal or penal justice, that it seems to fall almost outside of the province of administration, considered as a branch of government distinct from the judiciary. Yet the initial and the final stages of enforcement—prosecution and execution—are entrusted to organs of government which, while closely allied to the courts, are technically part of the executive government. A complete view of the field must not fail to take account of the important problems connected with the organization and action of administrative enforcing powers; but in the United States at least that aspect of administrative law has not so far received adequate systematic treatment.

ADMINISTRATIVE ORGANIZATION.

See ORGANIZATION, ADMINISTRATIVE.

ADMIRALTY. See MARITIME LAW.

ADOLESCENCE literally means growth, but as the term is used in biology and psychology it defines the period of human development from the beginning of puberty to the end of the maturation process. Its physiological characteristics are now well understood. Its chronological boundaries vary with race, climate, nutrition, social status and inheritance, and may include some individuals as young as eight and others as old as twenty-five. The status of an age group in society may be determined by studying, first, the scientific knowledge available concerning its physical and mental development; second, its position in the laws regulating social relationships, duties, immunities and privileges; third, its participation in social and economic activities and the problems resulting from the degree of adjustment or maladjustment; fourth, the moral and religious ideas that evolve concerning its conduct and status.

Thus infancy has been studied. In the pre-

natal period weight increases almost a billion-fold, in all the years after birth only about twentyfold. Most of the growth momentum, according to Minot, is lost at the time of birth (98 percent). The physical and mental progress of the first three years of life is in this sense infinitely greater than from six to nine or from puberty until twenty-one years. The significance of the growth rate in the life of the individual cannot, it appears, be stated accurately in terms useful for education, but there is a growing conviction that the period of infancy and childhood should be surrounded by special immunities and protection, and that its prolongation has significance for the more complete higher evolution of human beings. The status of the child in a given society is therefore held to be an index of social well-being. Undoubtedly the scientific study of child life has had a profound effect upon our modern social organization.

To set forth the position and the influence of the adolescent is a more difficult matter. Physically and mentally the normal adolescent is capable of approximating the adult role, as he frequently does among primitive peoples and pioneer groups. The adolescent can win his bread, produce offspring, fight and participate in social and religious activities. His immaturity comes to light in the more subtle phases of social life. He appears to be an adult yet he is not, and both primitive and civilized peoples have denied him complete political participation and have extended to adolescence some degree of immunity from adult legal and social responsibilities. Scientific evidence to support this "common sense" policy is vague because of a lack of systematic research into the norms of adolescent development. A scientific description of the normal adolescent in society remains to be written.

A study of adolescence has passed through four phases: first, interest in problems of physical growth and anthropometric measurements, which has resulted in the concept of physiological age; second, interest of the psychologist in individual differences and progressive development, leading to the concept of psychological age; third, the interpretation of these findings in terms of evolution, the "recapitulation theory," and the doctrine of adolescence as a "storm and stress" period; fourth, the definition of the problems of the adolescent in terms of the social situation.

Pioneers in the physiology and anthro-

pometry of adolescence were L. A. J. Quételet in Belgium (*Sur l'homme et le développement de ses facultés* in 1835, and *L'anthropométrie, ou mesure des différentes facultés de l'homme* in 1871); in Germany, K. von Vierordt (*Physiologie des Kinderalters* in 1877) and H. Vierordt (*Anatomische, physiologische und physikalische Daten und Tabellen zum Gebrauche für Mediziner* in 1888); H. R. Malling Hansen in Denmark (*Perioden im Gewicht der Kinder* in 1886); Charles Roberts in England (*Manual of Anthropometry* in 1878); N. Wiazemsky in Russia (1907); and Franz Boas, W. T. Porter, F. D. Burk, H. P. Bowditch and C. W. Peckham in America. G. Stanley Hall summarized these in *Adolescence*, a monumental work with extended interpretations as to phylogenetic and pedagogic significances. The most complete summary and analysis of physical growth studies was made by B. T. Baldwin, utilizing 5,385,400 recorded cases from all available sources in various countries. He found that oscillations in growth, in height and in weight occur before puberty. There is retardation in growth at the end of the pre-school period, a slight acceleration at about seven for girls and eight for boys, a marked decrease in the yearly percentile increment for girls at nine and boys at eleven, followed by the adolescent growth spurt which in boys culminates at the average age of fifteen and in girls from twelve and a half to thirteen years. The greatest mean variations in growth rate for both sexes are found during the characteristic adolescent ages for each. In a typical American rural community the pre-pubescent boys ranged in age from eight and a half to sixteen years, the pubescent boys from nine and a half to fifteen and a half years, the post-pubescent stage from eleven and a half to twenty-four years. In an analogous city group of boys the pre-pubescent ages were nine and a half to seventeen and a half, the pubescent ten to eighteen and the post-pubescent from twelve and a half to twenty-four years. The age of first menstruation for normal American girls ranges from ten to seventeen. Thus any study of the adolescent in society is complicated by its tremendous range.

Throughout the adolescent period there is acceleration in height, weight, breathing capacity and strength traits, with profound modifications of bodily organisms. Pubertal growth affects more or less simultaneously every part of the body, but not in equal ratio; for example, the muscles, the heart and the reproductive organs increase with great rapidity, the brain

hardly at all. Early puberty is followed as a rule by rapid cessation of growth in stature, although physiological processes of maturation may continue until the middle twenties. Growth statistics are of value for comparative study of masses of children in relation to age, sex, race and environment, but the growth status of an individual child cannot be evaluated from a study of growth averages, and therefore these early scattered investigations without uniform procedure or continuity have slight value for an understanding of the processes of normal physical development.

The experimental study of children of the pre-school age has been carried on by Baldwin in the University of Iowa and by Gesell in Yale, resulting in the establishment of norms of physical and psychological growth. Nothing of like nature exists for the adolescent. Helen Thompson Woolley in 1915 undertook in Cincinnati, Ohio, a study of 5483 adolescents from fourteen to eighteen, divided into two groups, at work and in school. Physical and mental tests were given to the same children each year for five years. The study was restricted to native born white children. For the first time in history records were kept of the physical and mental status of representative adolescents from year to year, their school or industrial histories, home conditions and where possible their social histories. The results of this study more nearly represent the situation in the community at large than any other ever undertaken with reference to adolescents. Formerly scales of mental development for adolescents were based almost entirely upon the selected group that remained in school. (Lodor, however, had previously studied the girl in the continuation school, and Leaming had developed tests and norms for vocational guidance at the fifteen year performance level. These studies compared school and work groups.)

The Cincinnati study included measurements in height, weight, vital capacity, strength of hand, steadiness, rapidity, eye-hand coordination, and a wide range of standard mental tests involving memory, perception, recognition, association, abstraction, reasoning, space perception, mechanical ingenuity. Comparison of working children with school children showed that in both physical and mental scales the latter are superior at every age level from fourteen to eighteen years. There is some evidence that mental growth continues to a greater age in the case of school children than among working

children. However, the information given by this study as to the laws of yearly growth in the mental development of adolescents is far from conclusive. The rate of growth, both physical and mental, is related to the various factors of age, sex, home background, degree of ability and type of measurements.

In fundamental physical capacities girls complete their period of rapid growth by fifteen or sixteen and gain very little after seventeen, thus reaching a status which is approximately that of the adult from one to two years earlier than boys. In mental growth no such sex difference appears. Boys and girls are closely comparable in their yearly gains in the few tests for which we have records. At present we have no data which set a limit in years to mental development for either sex, although the rather meager data from surveys of group mental tests incline some observers to think that average mental growth ceases at about fourteen or fifteen (Toops, Pintner, Ballard). The Woolley results indicate that improvement goes on up to sixteen or seventeen years. That social conditions play a part is evident. "It is a striking fact that the differences of home background, in these extreme cases, can not only counteract differences in mental ability, but can give to inferior children an advantage of three years in educational progress by the age of fourteen years" (Woolley, *An Experimental Study of Children*, p. 541). Degree of ability also conditions mental growth after sixteen; superior children tend to continue in mental progress longer than the inferior.

Although the concept of psychological age has been valuable in the field of education it has thrown little light upon the problem of the adolescent in society. The earlier writers, while noting that the death rate is comparatively lowest at this period, that growth abnormalities tend to diminish at puberty and that infectious disease is relatively rare, described adolescence as a period of marked instability and maladjustment. The dramatic appearance of puberty suggested that it was a new birth in which the higher human traits emerged. The disproportionate rate of growth of bones, muscles, various organs and glands suggested a corresponding mental and emotional disharmony, involving special dangers. In accordance with the doctrine of recapitulation, the adolescent was regarded as "neo-atavistic, prone to storm and stress," with "ancestral prepotencies struggling with each other for predominance." G. Stanley

Hall and his students circulated thousands of questionnaires on the subject of adolescent interests, diet, imagination, day dreams, recreation, love life, religious conversion and special abilities. Biographies of great men and women were studied and characteristics of their youth noted. From the studies Hall listed ten specific characteristics of puberty: first, inner absorption and reverie, "a double housekeeping of consciousness"; second, birth of the imagination, frequency of illusions, dreams, visions; third, self-criticism, skepticism and scruples; fourth, over-assertion of individuality; fifth, imitation at its acme; sixth, dramatic role at its height, poses, affectations, mannerisms; seventh, folly, absurdities, freakishness; eighth, new speech consciousness; ninth, absorption in friendship; tenth, impairment of orientation in time and place, intense fluctuations in energy, great emotional and intellectual plasticity. In summary, "we must regard the adolescent stage as especially characterized by . . . a loosening of the bonds between the manifold factors of our ego, somatic and psychic" (Hall, *op. cit.*, vol. i, p. 241). Thus the manifestations of adolescence were likened to the symptoms of hysteria and insanity. The recorded cases of religious fanatics are "adolescents in whom the tendencies and characteristics normal to this age are here seen only in persistent or exaggerated forms" (*ibid.*, vol. i, p. 266).

A more recent phase in the study of adolescence is the emphasis on its social aspect. The literature of the child guidance clinics and juvenile court studies points out that maladjustment occurs frequently in infancy and early childhood and is not more characteristic of adolescence than other periods. Where maladjustment is pronounced in the healthy adolescent it is now thought to be due to the social situation. W. I. Thomas gives evidence that when social norms and structures evolve more slowly than activities and inventions the result is a stage of disorganization, apparent alike in personalities and in society. When old habits are no longer adequate they break down, and before new habits are learned there is instability. Thus in the twentieth century youth appears to be in conflict with the standards of behavior in home, school, church and community. To add to the confusion, the dress, habits, activities and mood of youth are copied by adults so that the value of youth appears to have an exaggerated significance in social life, and the young have few recognized goals of

maturity to follow. At present infants and pre-school and school children are better cared for than in the past with reference to scientific programs of diet, sleep, exercise, physical safety and "chaperonage," while the adolescent is prematurely exposed to self-regulation.

More direct evidence that adolescence in itself is not a period involving special adjustment comes from the study of primitive youth, particularly that undertaken by Margaret Mead. The difficulties which we have ascribed to fundamental human traits are apparently nonexistent among such a group as the Samoans. Civilization imposes restraints on the one hand, and increased stimulation on the other. There is absolutely no evidence that the conflicts and difficulties of adolescence are inevitable. The behavior of adolescents in modern society, the symptoms of unrest and maladjustment, are no proof that these are normal characteristics of the age group.

Primitive peoples have often paid marked attention to the appearance of puberty in girls and boys and have endeavored through physical mutilations, ordeals, fasting, initiation, festivity, seclusion and instruction to mark it as an important threshold of life. Ceremonials of some sort are found in Africa, Asia, Indonesia, Australia, Polynesia, North America and South America. There are also groups of primitive peoples in the same areas who pay no attention to puberty. A systematic account of social activities among these peoples affords very little insight into the actual life of the individual. The picture is too standardized. How a given personality reacts to the prevailing culture is a matter for further research. The framework of primitive society appears to some observers to stereotype the youthful individual by powerful institutional devices which prevent him from self-expression. The anthropologist doubts the correctness of this assumption. Wherever a primitive culture has been studied intensively by one who knows the language and can penetrate into the life and feeling of the group, it is evident that the primitive treatment of adolescence takes account of the individuality of the adolescent and his need for independence. The new social status is seen in a variety of ways: change of dwelling, entrance into youth societies, ordeals, tests of personal skill and endurance, acquisition of a guardian spirit, the importance conceded to adolescent dreams and visions, separation from the family group, disappearance from home into forest or desert,

initiation into sexual life, freedom from childhood restraints, use of decorations, mutilations, serve as symbols of the enlarged status. The assimilation of the adolescent into the life of the primitive group is equally stressed by means of various modes of sexual, physical, social and spiritual initiation which tend toward the general phenomena of social symbiosis (Van Waters, *The Adolescent Girl among Primitive Peoples*, vol. ii, p. 90-91).

The more recent standards of adolescent conduct are difficult of scientific description. Programs of child welfare have been largely of extra-academic origin. It is not the scientist who has been directly confronted with problems of personal and social demoralization, but the parent, educator and social worker. The psychologist and sociologist have concerned themselves not with the difficulties the child makes but with the difficulties the child has. This has profoundly altered the method of approach.

Recent neurological studies have indicated that maturation is a subtle process, extending long after gross size and weight have been attained. Lawyers have recognized this and have hesitated to allow young persons the full management of large estates until they have reached the age of about twenty-five years. Legislation has lagged behind in matters of criminal responsibility, so that we see youthful individuals of fourteen, sixteen or eighteen held completely responsible for their deeds. Strict proof is lacking, but all studies seem to indicate that the integration of the nervous system is not complete until the middle twenties, whereas the conventional view that youth is mature at the time of political majority (twenty-one) prevails to the detriment of the individual adolescent. What we call wisdom and discretion are certainly not to be expected of the normal adolescent in his 'teens.

Among European and American civilized peoples the age of compulsory education has been extended to sixteen or eighteen. The state has definitely undertaken the academic and vocational guidance of adolescents. Youth is now definitely interested in programs of social betterment, war and peace, economic equality and democracy. The social situation is complicated, but youth remains the same—a period of life when physical and mental energy is at its height, when charm dominates, and the adult role is eagerly anticipated, yet when complete social participation is impossible because of fundamental biological immaturity.

As long as our social situation is somewhat pathological, youth will remain in conflict with prevailing social standards.

ADOPTION.

PRIMITIVE. Adoption is the legal fiction by which an individual belonging by birth to a certain kinship group acquires novel relationships that are reckoned as equivalent to congenital ones and either wholly or partly supersede the old ties.

Primitive conditions sometimes foster wholesale adoption of children. When a mother dies in childbed, the surviving infant must die of starvation unless a tribeswoman able to give suck is willing to adopt it. If there are no such women, the child is usually buried with the mother. At a later age a child may be easily orphaned by a war raid or the dangers incident to daily economic pursuits. Frequently the adopters are close relatives, such as uncles and aunts, but this is by no means essential. Among Plains Indian tribes a stranger who has lost a child bearing a real or fancied resemblance to the orphan may feel prompted to adopt it as a substitute. Other motives enter. Thus, where the concept of property is well devel-

oped, as among some of the reindeer herding Siberians, a childless man of wealth may find intolerable the thought of having his wealth dissipated and will accordingly take pains to find an heir.

In some regions of the globe, however, adoption is practised on a scale wholly disproportionate to any rational grounds therefor. In one of the islands of the Eastern Torres Straits group, children are adopted even before birth and brought up entirely in the family of the adoptive parent; often they never learn their real parents' identity. In the Banks Islands (Melanesia) similar customs hold sway. A newborn infant "becomes the child of the man who pays the chief helper or midwife at the birth." Since the father's sister determines the midwife, the father usually enjoys the best chance to establish his claims. But if he should lack the requisite fee or happen to be away, another man is likely to arrogate paternity and the true parents are not legally entitled to retain the infant. In theory the real father might indeed redeem his offspring at a later period, but practically the payments traditionally exacted—involving double the amount expended in the child's interest—prove prohibitive. This applies especially after the adopter has paid the boy's initiation fee for entrance into the men's society. Rivers interprets this extravagant tendency to adopt unrelated children as a sign of pristine community of children—itsself connected with a one-time sexual communism. However this may be, Oceania as a whole represents a main center for adoption carried to unusual lengths. In Polynesia childless Tahitians adopted children, and those blessed with progeny took over additional ones while giving away some of their own. In such cases the practise cemented the friendship of the households concerned, and the children themselves divided their time happily between their two homes. In this extreme form the custom inevitably modifies the principle of the universality of the individual family.

Adoption of adults occurs in a number of ways. A common one in North America is that connected with ceremonial affiliation. When a Hidatsa (North Dakota) buys entrance to a military society with his age mates, the group of sellers are collectively the purchaser's "fathers," irrespective of the magnitude of the difference in age between the groups, and each buyer has an individual "father," from whom he buys the relevant paraphernalia and instruction.

The logical consequences of adoption are generally carried out with astonishing rigor. If a man X adopts a boy Y in a matrilineal tribe, Y is reckoned as a member not of the adopter's clan but of his wife's: that is, he automatically falls into the group to which X's own children belong. Further, other individuals at once apply kinship terms to the newcomer in consistency with the assumption that he is X's son. In other words, X's brother (according to the common form of terminology found with clan organizations) calls Y "son" and expects to be called "father" by him; X's sister calls the boy by a distinctive nephew term and is reciprocally designated as an "aunt," and so forth. Adoption naturally leads to a fusion of diverse blood lineages, and the transition from a maternal family to a clan composed of two or more unrelated maternal lineages is most readily understood on this basis. Their distinctness is ultimately forgotten, and the fiction of a common descent welds all individuals into a single unit—just as in modern civilization community of political allegiance is constantly confounded with racial community. In latter day Hopi villages there are actually clans formed by a combination of several such lineages, both types being rated equivalent, regardless of the blood homogeneity or heterogeneity of their membership.

Primitive adoption customs rest on a mental attitude difficult to conceive for those nurtured in western traditions. Savages commonly have a generic love of children that is in no way dependent on a sense of consanguinity. A South African Negro insists on claims to his wife's offspring even when they are demonstrably begotten in adulterous intercourse. A Toda in southern India establishes his paternity by a fixed rite, and his wife's son, begotten ten years after the husband's death, becomes the deceased man's heir unless some other man has subsequently performed the ceremony. From all accounts the adopted child by legal fiction is in every case treated with all the loving-kindness lavished on a real child. If anything, he becomes the object of exaggerated tenderness.

ROBERT H. LOWIE

See: KINSHIP; FAMILY; MARRIAGE; ANTHROPOLOGY.

MODERN. Adoption was the ancient, as it is the modern; method of creating by law the relationship of parent and child. It is an old

institution in India and Japan. In Rome, since the religious headship of the family and the inheritance of property passed from father to son, the motive recognized by the law providing for adoption was the desire for an heir who would promote or continue the prestige of the family. The abstract rule was that adoption should imitate nature, and in consequence the civil law required that the adopting parent must be at least fifteen years older than the child adopted and must not be a relative within the prescribed limits of consanguinity. Adoption was carefully considered in the preparation of the Napoleonic Code, and with limitations the Roman provisions were followed. Other countries of Europe whose codes are based on the civil law have also with statutory modifications and with new safeguards followed the Roman law. Legal provision for adoption is now practically universal in Europe, Great Britain, the United States and Canada, but not so universal in South and Central America. The modern motive, however, is not the strengthening of the family but, as W. Clarke Hall puts it, the conferring of the "privileges of parents upon the childless and the protection of parents upon the parentless."

Legal adoption was unknown to the common law and was not authorized by statute in Great Britain until 1926. In English law the child had no absolute right to succeed to any part of the parent's property, but could be disinherited by will in favor of either relatives or strangers. It was possible, therefore, without resort to adoption, for family titles to be continued and family estates kept together when there was no direct male descendant. Provision for care of dependent children by means of adoption was probably delayed by the development of the relation of master and apprentice. By means of this arrangement orphans and children of indigent parents could be bound out, while the rights of the master and of the parent under this relationship were defined by law.

In the United States the first statute legalizing adoption as we now think of it was passed by Massachusetts in 1851. With local modifications the Massachusetts statute became the model for the laws which followed in other states, in Illinois, for example, in 1867 and in Kansas in 1868. Provisions for adoption by deed certified and filed as in a transfer of property were formerly not uncommon in the southern states and have been only recently repealed in Iowa and Pennsylvania.

Although the provisions of the present statutes regulating adoption vary from state to state, there are many similarities. The age of the adopting parent is seldom specified in the law. Louisiana, however, reflecting the influence of its early settlement, follows the civil law in providing that the person adopting shall be at least forty years of age and fifteen years older than the person adopted. A few states, among them Illinois, Minnesota, New Mexico and Virginia, provide that a person may adopt only a child not his own by birth. Almost all the states require the consent of the living parents of a child born in wedlock, and the consent of the mother of a child born out of wedlock, or the consent of the legal guardian of children whose parents are mentally incompetent, guilty of desertion or found by the court to be unfit to retain the custody of their children. In many states the consent of the legal guardian must be supplemented by that of a public official, the agency to which the child has been previously committed or someone appointed as a next friend by the court. As for the authority of the adopting parent over the adopted child, the laws usually provide that adoption establishes the legal relation of a parent to a child born in wedlock, including reciprocal inheritance.

The laws of the states make the welfare of the child of paramount importance in adoption, but with advancing standards of child care the concept of what constitutes a "fit and proper" home for dependent children has greatly changed. The best children's agencies now require that adoption be preceded by a careful investigation with a view to determining whether the child's physical needs will be met in the adoptive home, whether he will be morally safeguarded and given an opportunity for an education and the development of his capacities. They are also seeking with the help of the psychiatrist and the psychologist to determine whether the psychological conditions in the new home will not warp the child's development. This involves an examination of the compatibility and personalities of the adoptive parents and of the child. A trial period of a year or six months in the adoptive home is considered a necessary safeguard. In only a few states is the jurisdiction over adoption lodged with the Juvenile Court or Court of Domestic Relations. It has frequently been pointed out by students of the subject that the judge who is given this responsibility should understand

the problems which follow breaking up family ties and the transfer of children, and should have the resources for obtaining the information necessary for an intelligent decision as to what is in the interest of the children.

A movement to increase the safeguards established by law and provide administrative machinery for making these safeguards really effective has developed in recent years. A Michigan law enacted in 1891 was one of the first to require that the judge make an investigation before entering the decree of adoption; it was later amended to provide that the investigation should be made for the judge by the county agent or a probation officer. In Minnesota the court is required by statute to notify the State Board of Control when a petition for adoption is filed, and the board in turn must inquire into the condition and antecedents of the child and the suitability of the proposed adoptive home, and must submit a report of the investigation in writing to the court. New York requires investigation by some person or agency specifically designated by the court. In Massachusetts any judge of a probate court may appoint a guardian *ad litem* to find the facts in any proceeding relating to the care, custody or maintenance of minor children, while in Pennsylvania the court may cause investigation to be made by some person or agency specifically designated.

With the increased interest in safeguarding adoptions in the United States there has been at the same time a decrease in the number of children available for adoption and an increase in the number of foster parents desiring to adopt children. At present in the United States the practise of taking children from their parents solely on the ground of poverty is rapidly disappearing. Better wages, improved health conditions and workmen's compensation laws have prevented the break-up of many families. The so-called "mothers' pensions" or "funds to parents" acts passed in the United States and many European countries during the past twenty years, and the expansion and improvement of the work of children's agencies and family welfare societies, have also been major causes of this change in policy. Foster home care for children, as distinguished from institutional care, has greatly increased, and the work of children's aid societies in home finding, investigation before placement and supervision after placement has greatly improved. As a result the practise of receiving children in fam-

ily homes has increased, and foster parents have felt that the probability of a happy outcome in the event of adoption is greater. This has led to an increase in the demand for children to adopt. Although provision for legal adoption was not made in Great Britain until 1926, the practise of receiving children into their homes and rearing them as their own was not uncommon among the British, and such children were called "adopted" children. According to the report of the Committee on Child Adoption, 1921, there was concurrence among the witnesses who had experience in social work regarding a greatly increased demand for children to adopt, and hence a growing need for legal protection in adoption. The war and the epidemic of influenza in 1918 increased the number of orphans and of childless parents in many countries and led to an increased interest in adoption.

Records of child adoption are not as a rule separately kept by the courts in the United States of America, so that it is not possible to say how many petitions for adoption are approved each year in the United States. In Minnesota, where investigation of all petitions by a state department is required by law, the State Board of Control reports 701 adoptions in a two-year period from 1924 to 1926. Recent studies of adoption have given the information for several important urban centers. These indicate local variation in the numbers seeking to adopt children. Thus the report of the Children's Commission of Pennsylvania for 1925 points out that Allegheny County (Pittsburgh) has twice the number of adoptions in proportion to population as Philadelphia. On the other hand comparison of records of adoption in Suffolk (Boston) and Norfolk counties in Massachusetts with those in Cook County (Chicago) in Illinois shows approximately the same rate of adoption per 100,000 population for these counties.

While the percentage of children adopted in the United States who are of illegitimate birth is large, it varies greatly. Thus the studies referred to above showed that approximately 35 percent of the adoptions in Philadelphia County involved children born out of wedlock, in the state of Minnesota 44 percent, in Cook County, Illinois, 51 percent and in the Massachusetts counties 61 percent.

Incomplete reports from other countries indicate that adoption is probably much less frequent elsewhere than in the United States,

but is increasing since the war, and especially since the enactment of new legislation in recent years. For example, in France from 1910 to 1913 the average number adopted per year was 129; from 1919 to 1922 it was 267. In 1923, when new legislation facilitating adoption became operative, the number was 613, and in 1924 it was 1700. In Berlin, which has a population one third greater than that of Chicago, the average number adopted for the four-year period 1923-26 was 179. Pre-war figures for Berlin are not available. In Württemberg the number of adoptions per year averaged 55 from 1909 to 1912, but had reached 157 in 1919. For Sweden, which did not legalize adoption until 1917, the average number of annual adoptions from 1923 to 1926 was 941.

ADOR, GUSTAVE (1845-1928), Swiss statesman. Until the World War his career was typical of that of a successful Swiss politician. Having been elected a member of the municipal legislature of his township Cologny in 1871, he joined the cantonal legislature three years later and the federal parliament in 1878. For over thirty years before the war he played a prominent part in all Genevese affairs as a member and several times as head of the government, or as leader of the opposition when the conservative party, to which he belonged, was out of power.

When the war broke out he organized, as president of the International Red Cross Committee, the so-called "Agence des Prisonniers de Guerre" for the search of missing soldiers and for the establishment of relations between prisoners of war and their families. In 1917 he became a member of the federal government under somewhat dramatic circumstances, his predecessor Hoffmann having been obliged to resign because his attitude had been deemed incompatible with the recognized policy of Swiss neutrality. In 1919 Ador was chosen by his colleagues in the government to be president of Switzerland and in that capacity he visited Paris during the Peace Conference. He took an active part in the negotiations which led to Switzerland's joining the League of Nations while retaining her military neutrality. Ador resigned his federal executive office in 1919. Having completely retired from Swiss politics, he remained a Swiss delegate to the Assembly of the League of Nations from 1920 until 1924.

Being politically active all his life, Ador, whose main characteristics were honesty, practical common sense, fearlessness and tact, rather than original constructive statesmanship, found no time for scientific research or for writing of any kind.

W. E. RAPPARD

Consult: Traz, Robert de, *Gustave Ador* (Lausanne 1919).

ADULT EDUCATION is an inclusive term which, as it is currently employed, embraces within its meaning the following varieties of activity: continuation education; corrective education; functional-group education; and folk

schools or people's colleges. A term which includes so many varieties of educational endeavor must necessarily be ambiguous. There is, however, a marked trend in the direction of limiting the use of the term to projects concerned with functional-group education and folk schools or people's colleges.

Continuation education is a projection of education from adolescence into adulthood. In most cases continuation classes are conducted under the auspices of the public school system; since those taking advantage of this form of education are for the most part young workers, the classes are usually held in the late afternoon or evening. There is no settled policy regarding the curricula for such classes, but the trend in the United States has been predominantly vocational; academic, cultural and social objectives have gained during recent years.

Corrective education represents an attempt to offer adults an opportunity for the compensation of deficiencies in their earlier education. The emphasis here is again largely vocational; adults discover the need for some specific knowledge or skill which for some reason or other they did not acquire during childhood or adolescence; they begin learning in adulthood in order to relieve this deficiency. They may, of course, find these opportunities in continuation classes.

Functional-group education is frequently motivated by the desire of adults to secure education because of some urgency arising from their membership in a group. Danish farmers, for example, embarked upon a program of adult education shortly after the middle of the nineteenth century; they had been defeated in a disastrous war; they had lost their market for wheat and were hence compelled to make radical adjustments in agricultural production; at the same time they realized that these momentous adjustments could not be made by an illiterate population. Consequently they undertook to educate themselves as adults, as farmers and as citizens impelled toward a new nationalistic orientation. Likewise industrial workers of England in the early part of the same century recognized the necessity of further education, not merely to enhance their vocational opportunities but to render them more effective as trade unionists. Workers' education has since spread to all industrial areas.

Folk schools or people's colleges originated in Denmark and have continued as the most

conspicuous form of adult education in the Scandinavian countries and Germany. Similar institutions have lately come into existence in England, the United States and other countries. The folk school is a resident institution appealing largely to adults who are passing through the later stages of adolescence. The content is predominantly cultural and the objective is to orient students with respect to social, economic, aesthetic and historical factors of their environment. These institutions stand outside the academic system, require no entrance examinations and offer no degrees.

In addition to the above classifications are numerous other educational ventures for, by and of adults, which are usually regarded as a part of adult education. Those demanding special attention are: women's clubs, Chautauquas, lyceums, university extension, correspondence schools, libraries, museums and discussion groups. One of the latest groups belonging to this miscellaneous category is composed of parents; the bulk of parental education at present consists of groups organized for the purpose of child study. There is, however, a decided trend toward including all of the functions of parenthood in such education.

Adult education crosses the path of the social sciences at three points: its general philosophy, or, more particularly, its motivations, objectives and aims; its content, or the relation between its subject matter and existing cultural patterns; and its method, or its pedagogical and psychological foundation.

There is no unified philosophy of adult education, no agreement with respect to objectives and aims. This is, of course, not to be wondered at, since general educational philosophy is forever in flux. The debate continues between those who insist that all education, including adult education, can have but one legitimate aim, namely the intellectual growth of the individual, and those who with equal persistence contend that the aim should be social. The argument, stated in these terms, will never end. An individual's primary motivation to seek education as an adult may be conceived in individualistic, personal terms, but once he begins utilizing this education he finds himself in a social milieu. Indeed he cannot even participate in the educational experience without responding to, and initiating, social stimuli. The acute problem in this area of motivations and objectives is not rooted in the inquiry as to how the adult's education is to be

ultimately used but rather in what specifically motivates him at the moment. Adults seek intellectual growth because they believe in its effectiveness to endow them with greater power, with increased facilities for expressing themselves as personalities, with larger freedom; they wish to create, to appreciate; they desire to become better specialists or to reach beyond their specializations. Adult education needs no truer philosophy than to be alert in responding to this wide range of motivations. And if a special group, a collective unit, wishes to educate its members in order to enhance the total group's welfare, the result is merely a reenforcement of motivations.

The content for adult education is derived from individual and group needs; it is influenced by the sponsoring agency, the local setting, the availability of teachers and the intellectual capacity of adult students. In many instances the content for adult education represents merely an adaptation of academic curricula; in other cases adult classes and institutions have evolved their content by a process of conscious opposition to academic traditions. The exceedingly wide variation in subject matter existing at present makes generalization impossible.

The chief debate in this area of content revolves about the question: Shall adult education be cultural or vocational? The term "cultural" is used in this connection to denote subject matter which has no direct utilitarian purpose but which is intended to enrich intellectual and appreciative life. In Denmark, for example, the people's colleges undertake to teach only non-vocational subjects; their curricula are made up of such studies as literature, music, art, economics, history, etc. In the United States, on the other hand, the efforts of adults to improve their knowledge in order to enhance their vocational status are called adult education. Moreover, many subjects which are taught from the cultural point of view are discovered to have later vocational applications. The line of demarcation between vocational and cultural subjects is not as sharply defined as many believe. Any subject may eventually prove to have utilitarian value, and by the same token a vocational subject may lead to cultural considerations. The real essence of the problem of content lies in discovering what adults are prepared to learn rather than in determining what should be taught. From the sociological point of view, the curriculum should be derived from the impending adjustments

which adults are called upon to make in any given cultural situation. From the pedagogical point of view, subjects should begin where interest is alert and acute. And, from the psychological point of view, subjects for adult classes should be compatible with the intellectual levels of the prospective students.

Since adult education proceeds under the auspices of so wide a number of institutions and agencies, it is to be expected that there will exist also a wide variation in pedagogical method. An assemblage gathered within a huge tent listening to a noted lecturer is classified under the heading of adult education, and an individual pursuing a correspondence course is likewise placed in the same category. But between these two extremes lies the great bulk of that educational activity which is slowly coming to be called adult education, namely, small study groups or classes following a definite sequence of subject matter. Each of such groups is supplied with a teacher, and the method of learning is one in which students are stimulated and guided by the teacher. Often the teacher uses the same methods as are employed in ordinary schools and colleges. If there is anything distinctive about method in adult education, it is derived from the growing use of discussion. The discussion method has come to be the accepted learning process for large numbers of adult classes. It is, of course, a method admirably suited to adults; the teacher and the students are often on the same level of experience, and through discussion this experience is utilized as educative material. Moreover, adults are likely to desire a participating share in their education; they can achieve this much more advantageously through discussion than through reading, recitation and listening to lectures. The discussion method represents a social process; the entire group reveals through discussion not merely its knowledge but its feelings, interests and prejudices. It is, in short, a method of cooperative learning.

The so-called adult education movement assumed form and substance in the United States during the decade following the Great War. The Carnegie Corporation brought into existence an advisory committee, and in addition conducted several exhaustive surveys; a national conference was held in Cleveland under its auspices in 1925, at which time the decision was taken to organize an American Association for Adult Education. This organization has maintained headquarters in New York City

since October, 1926. Its functions are not primarily promotional or operative; it serves as a "clearing-house" for general information, sponsors studies, researches and demonstrations, and acts as a national coordinator for the movement as a whole. The researches which have resulted from both the Carnegie Corporation's activities and those of the American Association for Adult Education are listed in the bibliography below. From the point of view of the social sciences, the two significant aspects of research sponsored by the American Association for Adult Education are: community surveys conducted for the purpose of discovering the available educational opportunities for adults; and psychological experiments designed to reveal the educability of adults. With respect to the latter problem, Professor E. L. Thorndike concludes that general ability to learn rises until about the age of twenty and then, perhaps after a stationary period of some years, slowly declines; the decline is very slow, perhaps one per cent per year, and it is probably safe to say that adults under fifty should not be deterred from learning anything which they really need to learn.

ADULTERATION is the debasing of a commodity by admixtures of foreign, inferior or harmful material or by reducing its grade below that which it is represented to be, to the loss or disadvantage of the user, either in money or in service rendered.

Adulteration may increase weight or bulk, improve or alter appearance or flavor to simulate an article of higher grade or different kind. Sometimes a valuable substance is extracted and substitution made of a color or flavor which conceals the loss (e.g. skimmed milk given the appearance of creaminess by addition of a yellow dye). Sometimes one commodity is sold under the name of another (e.g. a mixture of low grade white flour and bran sold as graham flour).

In another class of cases poisonous, tainted or diseased material is mixed with sound (decomposed salmon tinned with fresh salmon). Defects may be concealed by special processing or packaging (tainted sausage disguised by strong spices). Factory made furniture is very commonly modified and finished to simulate antiques. Sometimes even worm holes are introduced into new lumber by ingenious devices, and a close imitation of the wear and tankard dents of centuries of European wassailing is produced on table tops in American mass production plants.

Recorded practises of adulteration date from the earliest times and have been in frequent evidence throughout the civilized world since the early Middle Ages. The methods and devices used have at all times drawn from the most advanced ideas of science and the arts, and important discoveries in chemistry have formed the basis for a whole system of adulterative practises—the use of artificial preservatives in foods, for example.

The reasons for adulterative practises are constant, and plain enough, but the technique is continually changing. The protection afforded the ultimate consumer (who is given no practicable redress under the common law) varies from no protection at all in some countries and states to fairly effective safeguards for commodities that enter into interstate commerce and which, moreover, affect life or health. These include food and drugs, but not cosmetics; seeds and fertilizer and insecticides, involving the

welfare of a large agricultural population; and a few kinds of goods, such as soap, when infrequently the question of unfair competition brings the matter into issue before the Federal Trade Commission in the interest primarily, not of the public, but of competitors who are put at a disadvantage in the market..

In a very limited class of commodities, such as meat and milk, a considerable degree of protection is afforded, in a very few states, even when production and distribution are intrastate. In many jurisdictions, however, such control activities as exist are dealt with by public authorities more as a political football than as a problem for technicians.

Adulteration appears as a factor in every kind of merchandise. Fugitive and water-soluble dyes are substituted for permanent pigmenting materials in ordinary writing ink and in textile fabrics; castile soap is made with fats far different from, and cheaper than, olive oil; inoperative or "dummy" vacuum tubes are introduced into radio sets because such sets are commonly valued by the buyer on the basis of the number of tubes employed; illuminating gas is reduced in heating value by admixture of inert gases; electric lamp bulbs of the inefficient carbon filament type are made to simulate the modern efficient tungsten lamps; and reworked wool, or shoddy, is used as a cheap and non-durable substitute for virgin wool in clothing. Most of such adulterations go undetected by an overwhelming majority of consumers, but are not likely to elude inspection by the government or by the few hundred of the more progressive manufacturing corporations which conduct elaborate and costly tests to protect themselves against commercial cheating. Against such large scale frauds as the substitution of inferior woods for mahogany in furniture, of inferior, split and artificial leather for real leather in luggage, and of hare and woodchuck furs for sable, fox, mink and skunk, the ultimate consumer has no practicable mode of protection under the going structure of law, administrative government and industry. Unfortunately middlemen or retailers, who nominally act as the purchasing agents for the consumer, have only to a negligible degree offered him assistance in his increasingly varied and difficult problems of purchase.

The amount of technical and legal activity required even for the moderate amount of food and drug control work that has been carried on in the United States since 1906 can be judged from the fact that, under federal control alone,

which is limited to interstate commerce and imports, about 25,000 cases have been reported to the legal arms of the government for court action, and decisions have been handed down in 16,000 cases. Imported goods have been proceeded against in nearly 200,000 cases; 300,000 food and drug samples have been collected and examined.

The practical control of adulterative practices of all kinds depends first upon standards—that is, accepted uniform definitions and requirements; and second, upon an active and coordinated system of inspection, examination and test based upon those standards. The common adulteration of paint, for example, with all sorts of inferior oil vehicles and mineral "extenders" and inert powders, like whiting and ground flint, remains impossible to control in the public interest until a proper paint for a given purpose has been described and defined in precise and reproducible terms in the form of a standard specification. As yet comprehensive specifications for paint are practically available only through their use by the federal government in its purchases.

Such a national system of specifications already exists for many of the more important food and drug products. For other consumers' goods, standards are largely lacking or, if in existence, are not in common and recognized use. Their growth in the future will probably depend largely upon such national and governmental standardizing agencies as the U. S. Bureau of Standards and the American Standards Association, a federation of forty organizations made up of seven government departments, twenty-three national industrial and trade associations and ten technical societies.

It seems probable that the wide development of such standards must wait upon a considerable and articulate public demand. The development of this demand will very likely depend upon educational activities conducted by one or more of the great foundations. There is not—and perhaps there cannot be, with the present American political structure—any other powerful organized group of a sort having a predominant and financially potent economic interest in the improvement of the consumer's status as to the quality of the goods which he buys. Reform, where it has occurred in the past in a few special fields, has followed exposure of very bad practices so extensively pursued as to characterize, in effect, a whole industry or group of industries, and so to lead to a radical legislative remedy

in the protection of public interest and welfare.

ADULTERY. *See* MARRIAGE; FAMILY LAW.

AD VALOREM AND SPECIFIC DUTIES.

A duty levied as a fixed percentage of the price of an imported article is called an ad valorem duty. A duty levied as a fixed number of cents or dollars per pound, gallon or other unit is called a specific duty. The duty on the standard grade of sugar when imported from Cuba—1.7648 cents per pound in 1928—is a specific duty. The equivalent ad valorem duty, when the selling price in Cuba is 2.2 cents per pound, would be about 80 percent. If, however, the price should advance to 3 cents per pound, the equivalent ad valorem duty would be reduced to about 59 percent.

Specific duties are sometimes supposed to be more acceptable to protectionists and ad valorem duties to free traders. There is no necessary connection. Ad valorem duties may accord a high degree of protection, and specific duties may be very moderate. However, in the United States tariffs enacted or proposed by the political parties advocating high protection have in general been characterized by a preponderance of specific duties, while the reverse has been true of the tariffs enacted or proposed by their opponents. One reason is that a high measure of protection may appear less offensive when expressed as a specific rather than as an ad valorem duty. For example, consumers may not appreciate so keenly the burden of the duty

on sugar when expressed as 1.76 cents per pound as when expressed as 80 percent ad valorem.

There are two other reasons why protectionists prefer specific duties. First, when prices are falling and in consequence the need of protection is more keenly felt, an unchanged specific duty assures a constantly increasing rate of protection, as indicated by the ad valorem equivalent. Second, when the price of the protected article is subject to violent fluctuations, an ad valorem duty gives the least protection, as measured by the difference between the domestic and foreign price, when prices are low and protection is most needed; and the greatest protection when prices are high and protection is least needed. That is, the benefit from an ad valorem duty varies inversely as the need for such benefit.

The bearing on protection of these two methods of assessing duties is not the only factor to be considered in choosing between them. Ease of assessment and lessening of the likelihood of fraud are factors. The amount due when the duty is assessed by the pound or other unit is easily ascertained and is unequivocal. On the other hand, when the duty is ad valorem the amount due the government may be open to doubt. Such duties are usually assessed on the foreign price as shown by the invoice. But this may be based on a false valuation, and cannot be checked by an independent survey except at considerable trouble and expense.

To overcome the danger of fraud the domestic price has been suggested as a basis for computing ad valorem duties. A strong effort was made in the Act of 1922 and again in 1929 to substitute American valuations. As proposed by advocates of the change, American valuation may be based on the "United States selling price," that is, the price which an importer would pay for the article laid down at an American port before the duty was paid, the price of a similar competing article in the United States or the cost of production in the United States of a similar competing article. It is to be observed that these three bases are not identical. The value arrived at by the last two methods should exceed that arrived at by the first method by approximately the duty.

Advocates of American valuation stress the alleged frauds of undervaluation arising from our present method, the difficulties which appraisers experience in checking the foreign prices submitted by importers as a base for

reckoning the duties which they propose to pay, and the virtual espionage on foreign soil frequently involved in making this check. Such methods, they claim, are a source of international friction.

Opponents of the change minimize the importance of fraudulent undervaluation. They assert that custom house statistics reveal that less than one tenth of one percent of the entries were intentionally undervalued. They deny that the change would contribute to efficiency, asserting, on the contrary, that whether the merchandise is purchased outright (in which case the invoices are documentary evidence of market value) or sold on consignment, the appraisers are in a position to determine more speedily and accurately the base on which the duty should be computed than under any plan of American valuation. They point out that a large part of the imports are of goods that are not comparable with any goods being sold in the markets of the United States. They claim that the change would work a serious hardship to merchants and importers: under American valuation the latter would be unable to estimate the duty in advance and hence their business would become hazardous and speculative. Finally an abstract argument against American valuation is that it would give an administration biased in favor of manufacturing interests a dangerous power of "flexing" the tariff in their behalf.

Back of all these arguments is the fact that under American valuation a high duty may be concealed under an apparently moderate rate. American valuation therefore appeals to protectionists. It is significant that at the congressional hearings the advocates of American valuation have been representatives of manufacturing interests, while those opposing the change were representatives of importers and commercial interests.

However, aside from any question of fraud, some articles lend themselves to one type of duty and some to the other type. Standardized articles, such as wheat, pig iron and sugar, lend themselves to specific duties. On the other hand articles presenting a wide range of qualities and values, such as textiles, lend themselves to ad valorem duties. Frequently to secure the uncompromising precision of the specific duty and yet retain something of the flexibility of the ad valorem duty, a series of specific duties, each limited to a range of values, is imposed. For example, in the United States

Tariff Act of 1922 the duty on steel bars, valued at not over 1 cent per pound, is $\frac{2}{10}$ of 1 cent per pound; valued above 1 cent and not above $1\frac{1}{2}$ cents per pound, $\frac{3}{10}$ of 1 cent per pound; and so on by ascending steps to a value exceeding 16 cents per pound, when the duty becomes 20 percent ad valorem.

ADVERTISING. Originally the term signified communication or the conveying of information, but advertising is now most commonly thought of as involving persuasion of some sort as well as information. It is impossible in discussing modern advertising and its institutional arrangements to keep political, religious, educational and other propaganda wholly separated from trade publicity.

As communication rather than persuasion, or at least persuasion to buy, advertising had its earliest recorded use in ancient civilization. Descriptions of runaway slaves and proffered rewards for their return, written on papyri more than three thousand years ago, have been uncovered in the ruins of Thebes. Advertising communication was not limited to written forms, however, in early civilization. The crier of goods for sale and of rewards for the discovery of possessions or persons lost appears to have been common in ancient Greece. Venus herself, according to tradition, engaged Mercury for the latter purpose. The Romans made no small use of advertising. Professional men publicly offered their services on their house walls. Painted notices that property was for sale or lease appeared on doors of buildings. Excavations in Herculaneum and Pompeii have disclosed painted wall signs picturing gladiators and urging attendance at their exploits. Other walls advertised plays, and still others baths—"warm, sea and fresh water."

The general illiteracy of Europe in the Middle

Ages and the limited channels for the movement of ideas of any sort made criers the chief medium of trade publicity. Criers became a national institution in England and also in France, where they formed an organization as early as the twelfth century, perhaps an early illustration of an advertisers' association. In both countries they were employed by shop and inn keepers. The wine criers of Paris not only attracted attention with their horns and their voices but also offered samples of the ware proclaimed.

The seventeenth century in England must be stressed even in a brief history of advertising, for it foreshadowed nearly all that has come since. In the early part of the century billing was the chief form used, with St. Paul's Cathedral, according to Sampson, as the most popular place for posting, and personal services, runaway servants, quack medicines and books as the most frequent subject matter. Ben Jonson, with a ridicule for book advertisers which amusingly contrasts with certain current book selling efforts, enjoined his bookseller to sell his works for wrapping paper rather than by the common means. The earliest advertising in newspapers in England came also in the seventeenth century with the rise of the "mercuries," as the newspapers of the day were called. Among early examples is one with a rather modern sound: "Warhams Excellent Mouthwater, which . . . preserves the Gums and Teeth, takes off all smells proceeding from bad teeth, etc. Is prepared and sold only by W. Strode . . . Tottenham Court Road. . . ." It is interesting to notice the extent to which early English trade advertisements proclaimed nostrums which could not fulfil the claims made for them; and books which no man can describe accurately for another; and new commodities to which, if they were to be sold, favorable attention had to be drawn by such devious devices as the testimony of imaginary physicians.

The modern manifestations of advertising are to be accounted for only in terms of the patterns of economic and social life of which they are parts. Modern advertising is part and parcel of the whole set of thought movements and mechanical techniques which changed the mediæval into the modern world. In its full history it must be related to the Renaissance; account must be taken of the growth of reading, the development of schools, the advent of public education and the eventual development of an all but general literacy. Advertising is related also to that decreasing commercial use of pack

horses throughout the seventeenth century which made transport by wagon and cart "wonted practise" by 1700. It is related to the continued development of transportation by clipper, steamer, train and airplane. The history must include the inauguration of a postal system, another great feat of seventeenth century England, and its expansion and improvement. The growth of publications must be followed from the meager beginnings mentioned above to the present number and variety. The story of these changes must be interwoven with that of changes in knowledge and techniques. The development of road materials, of iron, of steel, of paint, of paper, of ink must all be included, and also a consideration of the significance of steam, electricity, radio, photography, and expanding skills in printing, etching, plate making, news gathering, appealing. All of these, in both their early and later development, are important because they make possible the economic basis of advertising—because they are features of the economic order of which advertising is a part.

The rise of advertising coincidentally with the reorganization of industry in the seventeenth and eighteenth centuries indicates its economic basis. In a world of self-sufficing individuals or groups it is of little importance that one knows what others do or plan to do. In a world where producers specialize, it is all important. Without such knowledge specialization cannot be carried on. In so far as advertising is relied upon for information, it may be said to be fundamental to specialization, for information is fundamental in relating and integrating the specialized units of our production system. Advertising furnishes significant information in two areas. One may be called the trade area. Business men advertise to other business men. As business always involves buying and selling materials or goods or services or some or all of them, mine operators, railroad companies, farmers, manufacturers, merchants, financiers, risk takers and advertisers are anxious to be informed of sources and outlets. Chiefly through trade publications all of these advertise to give or secure this information. The second area in which advertising furnishes information is the consumer area. The consumer, being a specialist, often producing nothing which he himself can use, needs information as to what has been made available for him. His trust that information and goods will be available is what makes it possible for him to specialize. Even considering the wide display of possible purchases now put before most consumers by de-

partment stores and other retailers and the army of specialty salesmen, advertising in printed form provides more information than any other agency. The necessary reliance of business man and consumer upon advertising raises the possibility of a misplaced faith. A discussion of this is best postponed until we have considered the organization for creating and distributing advertising.

The institutional machinery of advertising is massive and complex, since the conveying of economic information has become as much a business as those businesses which it serves. The advertising mechanism in America consists of three chief divisions: first, those enterprises which devise and operate media for carrying publicity; second, the agencies which relate the advertisers to the media; third, an unclassifiable list of supplementary businesses. The media through which advertising may be carried to prospective buyers are many, but they are chiefly newspapers, magazines, outdoor facilities, car-cards, theater films and programs, radio and direct mail material. All except the last are called the media for general advertising. Each of the media of general advertising is itself an enormous business. There were in the United States in 1927 some two thousand dailies, eleven thousand news weeklies and several hundred semi-weekly newspapers. There were approximately seven thousand magazines and periodicals, of which about four thousand were monthlies. The value of a periodical for advertising varies with its circulation and its quality. The latter, for a specific purpose, depends upon many factors, varying with the article for sale and the age, sex, taste and purchasing power of readers. The specialization of magazines aids the advertiser, such magazines as *Furniture Age* and *The National Grocer* reaching different readers from those subscribing to *Farm and Fireside*, *Advertising and Selling*, *The Dental Digest*, *Golfers' Magazine* or *The American Boy*. Announcements of the extent of periodical circulation are now usually dependable. The chief agency for authoritative statement in this field is the Audit Bureau of Circulations, an organization comprising advertisers, advertising agents and publishers.

The most important forms of outdoor advertising are posters, painted and electrical displays and occasionally sky writing by airplane. Posters are now usually of certain standard dimensions adapted to standard poster boards, of which

there are several hundred thousand in the United States. Painted display, a highly organized business, is the modern elaboration of the advertising with which the residents of Pompeii were familiar. The "wall," which is still frequently used literally, has in many other cases become a "bulletin"; that is, a wall constructed solely for the purpose of painted signs. Many of these are now built of small sections that may be taken down and painted indoors. "Painted copy" usually "runs" for several months. Electrical displays in their many bizarre forms and sky writing need no description.

Car-card advertising has been made significant by the developments which compel thousands of people to travel upon street cars or suburban trains every working day. Development of the business of confronting travelers with urgent proposals for expenditure has led to a standardization of cards and "runs." Advertising on theater programs and more recently on moving picture films constitutes a large business. The advent of the radio has reintroduced the crier, galvanized and glorified. "Time" is purchased from radio broadcasting companies and is utilized usually for the broadcasting of excellent programs with minor comment of an advertising character. To these media might be added many miscellaneous types of general advertising, including window display, novelties and business shows.

Advertising which goes directly from advertiser to prospect is called direct advertising. Its technique consists first of selecting likely prospects and second of devising mailing pieces calculated to secure the desired results. Mailing pieces are often planned as a series which, directed to the prospect one after another, are intended to find any possible weakness in his disinclination to buy or take advantage of impressions earlier made. Direct advertising is the sole instrument of some advertisers, although it is more commonly used in conjunction with general advertising. Special concerns are equipped to plan and execute any or all phases of direct advertising.

The most important single unit in the American advertising machine is the advertising agency. This institution has become a highly specialized middleman acting between the advertisers as buyers and the media as sellers of space. While some advertisers carry on every function of the agency for themselves, the larger ones usually rely on agencies. The agency in America had its beginnings before the Civil

War in certain "agents" who, contracting for space in publications, resold it to manufacturers or other advertisers. The agency now represents the advertiser rather than the space seller, buying for his client such space in media as he believes useful in any given case. The agency, however, receives its remuneration from the publications in the form of a recognized 15 per cent commission. The fully developed modern agency is far more than a middleman dealing in space. It has become an institution which carries all the advertising tasks of the advertiser. Agency operations commonly include: first, securing the "accounts" of advertisers; second, conducting investigations of the products concerned and of markets, media and methods; third, planning the advertising, which often takes the form of a campaign or a series of campaigns and may be combined with a merchandising plan also devised by the agency; fourth, preparing the copy; fifth, selecting the media, giving attention, among other matters, to size and dates of showings and relationships to other aspects of the merchandising plan; sixth, constructing the plan of illustration, type, lay-out and the like, and often looking after the physical production of drawings, etchings and type plates; seventh, aiding in "merchandising the advertising," which consists of interesting salesmen, dealers or others involved in the merchandising activities.

The advertising agencies have been responsible for a very large part of whatever degree of science has found its way into advertising. Their research departments, manned in some part by men trained in the tools of the social sciences, have seriously endeavored to reduce guess work. Together with certain periodicals they have gathered, and encouraged governmental agencies and trade associations to gather, data which make it easier to estimate the needs, wants and abilities to pay of various parts of the population. All of this, however, has not always made advertising profitable. Although numerous examples of great success achieved through advertising are cited, the possibilities of determining in advance the profits to be derived from advertising leave much for the business man to desire. The statement of one leading agency that it "practises advertising as an almost exact science," is reminiscent of Dr. Johnson's statement in 1759 that "the trade of advertising is now so near to perfection that it is not easy to propose any improvement." Advertising is probably no nearer an exact science now than it

was near to perfection then. It remains a matter of strategy rather than of scientific certainty.

The adjuncts of the principal advertising mechanisms include businesses or industries concerned with printing, paper making, copy writing, advertising art, electrotype manufacture, photography and many other activities. Any of these may be integrated with a medium or an agency or may operate independently. Trade associations bind together for mutual benefit several divisions of the advertising world. The most inclusive is the International Advertising Association. This organization has recently established a Bureau of Research and Education for purposes implicit in its title.

Although the institutional machinery of advertising is more developed in the United States than elsewhere, it has advanced in all countries that have been touched by western economic methods, taking patterns similar to those described. English styles are closest to our own. The complete sales appeal is less developed in continental advertising; but in publicity, especially through distinctive posters, Germany and particularly France are notable. Trade publications are better in Germany than elsewhere in Europe. The farming out of space is still common, and Americans find circulation figures less satisfactorily checked than at home. In South America and the Orient advertising is expanding; Japan, in fact, is on a footing with England and the United States.

The usual measure applied to advertising costs is the gross amount paid for the various media. There are no authentic figures to be had, but persons in a position to have reasonably accurate information estimate the total outlay in the United States for 1928 at between one and a half billion and two billion dollars. The same sources make more detailed estimates as follows: newspapers, \$765,000,000; magazines, about \$191,000,000; business papers, \$95,000,000; outdoor media, \$80,000,000; theater, \$1,600,000; direct mail, \$450,000,000. This leaves street car, radio advertising and samples uncounted. From such figures of the "white space sales" of media, erroneous conclusions are frequently drawn. They are used to illustrate the high cost of selling. This neglects the cost of alternative methods. Advertising is ordinarily used because it is relatively inexpensive. The same deduction overlooks the space bought by educational, religious, charitable and political organizations for propaganda purposes. In a campaign year the latter is large. Moreover, a

large offset must be made for other services performed by the same expenditure. Much of the cost of newspapers and magazines, for example, is paid for in advertising receipts.

It has been suggested above that selling takes place in two areas: selling to the trade, that is, to extractors, manufacturers, railroad companies, financiers, risk takers, advertising institutions, merchants and other specialized producers; and selling to consumers. In the first of these areas there has been little questioning of the social merit of advertising. It is assumed that the trade buyer is sufficiently pecuniarily minded and sufficiently informed to protect himself.

Against consumer advertising, however, several charges are made. First is the declaration that dishonest and fraudulent advertisements lure large sums from customers. Investigations by the American Medical Association and the Federal Trade Commission justify the conclusion that these charges are well based. Chairman Humphrey of the Federal Trade Commission, admitting that there was no method by which the amount could be accurately measured, estimated, in 1928, that the amount taken annually by fraudulent advertising was more than five hundred million dollars. The greatest portion of this he believed to be drawn from the sick, the poor and the ignorant through advertisements of medicines, cures, fake schools and the like, although other credulous persons contribute heavily. Fraud by advertising and using the mails to defraud are clearly unlawful, and both the Department of Justice and the Post Office Department have acted with vigor but without complete success. The Federal Trade Commission in the autumn of 1928 organized, with the cooperation of publishers, an attack upon fraudulent advertising and the publications which carry them.

Advertising interests have by no means been wholly lacking in the past in actions against untruthful advertising. A number of publications carry a guarantee of the reliability of all advertisements that appear in their columns. Many individual publications censor all advertising submitted and suggest the modification of objectionable copy or refuse it. A model statute for the prevention of fraudulent advertising was drawn up in 1911 under the direction of *Printers' Ink*, probably the most important trade publication in the advertising world; and this law, or a modification of it, is now in effect in most of the states. A National Vigilance Committee which was con-

cerned with enforcement of the law was organized in 1912 by the Associated Advertising Clubs of the World. Its work was later largely taken over by the Better Business bureaus, national and local, which also played a part in the plans of the Federal Trade Commission. Although, as one advertising man comments, "the war against untruthful advertising has been long and bitter," the end of the imposter, the fraud and the cheat in advertising is not yet. One continuing difficulty is to distinguish between what is outright fraud and what is misrepresentation and near fraud.

A second charge against advertising is its alleged vulgarity. This takes various forms. A more specific charge is that advertisers disfigure walls, sidewalks and scenery and force a brash and garish intrusion upon our senses. England has for many years felt the need of regulating the advertiser's willingness to press his interests upon the attention of the public. As early as 1853 advertising vans were prohibited in London, and the sandwich man has long since been moved from the sidewalk to the gutter. There was formed in England in 1893 an organization called the Scapa, the National Society for Checking the Abuses of Public Advertising. In France, Germany, Switzerland, Italy, Austria, Hungary, the countries of South America, and the United States as well, regulation of billposting has been necessary. These regulations in some instances are left to a general police control. Some specifically forbid the disfigurement of landscapes. In other instances laws protect public monuments and limit the size and height of billboards. In the United States such regulation is for the most part in charge of the municipalities. Advertisers contend that in cities their billboards are far more sightly than the vacant lots and rubbish piles which they sometimes hide. Their case is perhaps weaker when they are charged with the concealment and disfigurement of rural scenery, which was satirized recently in the verse:

Along the country roads there grow
Willow trees and Texaco,
Mobiloils and marigold,
And other fruits of men and mold.

Another alleged vulgarity of advertising is found in its insistent appeal to mankind's lower or less admirable motives. A casual survey of advertisements in the most commonly read general or women's periodicals discloses frequent attacks upon the prospect through his fear, shame, vanity, ostentation or snobbery. It is

surprising how frequently such motives are appealed to by reputable concerns selling reputable goods. Many concerns also rely upon testimonials (bearing all the earmarks of being solicited and paid for) of movie stars, pugilists, society leaders, professional ball players and minor representatives of royalty. It is all the more depressing to realize that even after study advertisers find such motives the most moving and such methods the most effective. That these motives and methods are not limited to America is indicated by the remarks of a prominent English advertising man who, in commenting enthusiastically in 1928 upon a campaign based on emulation, said: "If you would sell cars to the British public, appeal to their sense of snobbery, create a definite class appeal. Tell them how many kings and queens and bishops and right honorables are using your car."

The study of the psychology of advertising, which has had a good deal of attention and discussion for two decades, together with the experiences of advertising writers, has produced several classifiable methods of approaching readers. These include emotional copy, "reason why" copy, narrative copy, human interest copy, testimonial copy, suggestive copy. These are ways of dressing the so-called appeals. The appeals themselves must inevitably be to human attitudes, ideas, emotions, instincts or ways of behaving, according to the kind of psychology one has in mind.

The criticism often made that advertising exercises a control over the consumer's mind and choices is more or less implicit in the foregoing. One specific form of alleged control is a monopoly created by impressing a brand upon the consumer's consciousness. Since ancient Egypt makers have attempted and succeeded in doing this with trade marks. The consumer is in part exploited, in part protected by this. While a widely advertised brand by no means always indicates the best obtainable, it does in a great majority of cases indicate dependable goods. Moreover, although the consumer does not know in any technical sense what a brand means, he can be reasonably sure that successive units will be of uniform quality.

The competitive waste of advertising competing brands, perhaps equally good, is of concern to every student of advertising. So it was more than two hundred years ago. There has even been improvement, if one is to believe what Addison wrote in the *Tatler* in 1710: "... above half the advertisements one meets with

now-a-days are purely polemical. The inventors of 'Strops for Razors' have written against one another for several years. . . ." Of this waste, if waste it be, it must be said, as might be said of all struggles for the control of the consumer, including even the modern giant struggles of trade associations, that the waste is not in advertising but in the competitive system. If industries must battle in the market, printers' ink, paper and advertiser's art are the cheapest ammunition in the arsenal of sales effort.

But the criticism of control takes a more general form. Advertising is charged with an influence upon the habits of consumption and the standards of taste of the consumer. There is no doubt that there is such an influence. The millions spent on consumer advertising have no other purpose; and, although many appeals prove ineffective, the millions are not all spent in vain. The question whether this influence is desirable or undesirable is not so easily dismissed. It raises issues of a fundamental sort. The question involved is, how shall the standards of life be determined? The criticism of the advertiser's influence on the consumer's mind is usually based on the theory that the consumer is capable of knowing what he wants without outside suggestion. This theory is clearly untenable. What one comes to call the good life is determined by post-natal influences. The problem is, what shall the influences be? It may be said that whoever devises and directs the influences, it should not be those who are themselves influenced by a view to profit. This is a satisfactory generalization until one asks: Who should be responsible? How should the responsible agents be selected? How should they be compensated?

In eras when society was not able to produce beyond bare necessities, tradition, the medicine man and priest may have been satisfactory guides to the courses which life should take. But the great development of advertising came concomitantly with a reorganization of social production machinery. As an almost necessary part of the increase of production there has come an amazing invention of consumers' goods. New resources, specialization and the machine have produced not only more wealth but vastly greater variety.

Advertising, in spite of its costs, has proved itself an economical tool in the modern business system for bringing information as to possible choices before the many possible buyers. It has been used to urge upon every specialized

producer whatever has become available for use in production technique and upon every consumer whatever has become available for consumption. But the few standards for a narrow physical life which the consumer may have developed in a simpler day have been not so much erased by the flood of advertising rhetoric as they have been submerged in the onrush of improvements and overwhelmed in the torrent of variety. While by no means all materials or goods which were made a generation ago, and are still made, have been improved, how can the standards which guided either maker or user among the relatively few choices of that day be anything but impotent before the technique and diversity of today? Where opportunity to profit seemed possible, advertisers have honestly and accurately, or inaccurately and dishonestly, as the case might be, informed business men and consumers of the possibility of choice. They have used truth, deception, cajolery, vulgarity—almost every method known—to show and to persuade. They have in part, although by no means entirely, accepted the crude consumption standards of a crude world and appealed to them with crude methods.

But this great advertising activity has been largely due to the fact that advertisers have accepted increased productivity and, more important, its corollary, increased consumptivity. In accepting the first, they have often found it necessary to "go to the country"—the consumer—to secure acceptance by producers of important technical improvements. In accepting consumptivity they have been alone. The bankers have preached investments; the economist has taught saving; the schools have inculcated thrift. Our tradition is a tradition of careful frugality. The pillars of our society were built for a society of strict economy. No agency with a public interest was ready, with the coming of the new productivity, to encourage or guide in the enjoyment of the new wealth; nor has any since been ready to point the way to good use. Only now the economist is beginning to wonder if saving cannot go too far; if more spending may not be good even for production.

Consumer advertising is the first rough effort of a society becoming prosperous to teach itself the use of the relatively great wealth of new resources, new technique and a reorganized production method. Whatever eventually becomes of advertising, society must provide some device for this task. Some agency must keep before the consumer the possibilities resulting from con-

stant advance, for the world appears to be learning to produce goods ever faster. Today the voices crying most loudly in the wilderness of consumption are more concerned with noisily advertising the weaknesses of advertising than with the patient teaching of standards of taste which will reform advertising by indirection. Other action is possible. An increase of government specifications would help, although not as much as is often thought, and they would require an enormous amount of advertising. What is most needed for American consumption is training in art and taste in a generous consumption of goods, if such there can be. If beauty is profitable, no manufacturer is desirous of producing crudity or vulgarity. Advertising, whether for good or ill, is the greatest force at work against the traditional economy of an age-long poverty as well as that of our own pioneer period; it is almost the only force at work against puritanism in consumption. It can infuse art into the things of life; and it will, if such an art is possible and if those who realize what it is will let the people know.

ADVISORY OPINIONS.

NATIONAL. The historical relations of the English judges to the Crown and to the House of Lords explain the practise by which English judges gave opinions upon legal questions extrajudicially, that is to say, otherwise than as judgments. Since the English king was the fountain of justice and since the English national courts evolved from the *curia regis*, the English king retained the power, when acting

in his judicial capacity, of consulting his judges. The Privy Council, to which the monarch's judicial powers came to be delegated, likewise consulted the judges; and when in 1833 Parliament created the present Judicial Committee of the Privy Council (3 & 4 Wm. IV, c. 41), the duty was conferred upon it of advising the Crown on legal questions. Similarly from the king's power to compel the attendance of his judges in the *curia regis* there grew up the practise of calling on the judges to advise the monarch in his executive capacity. By 1770 this power was well recognized, although ten years earlier the judges had announced that they would not be bound in litigation before them by extra-judicial opinions previously given [Sackville's Case, 2 Eden 371 (1760)]. Since the establishment of the Judicial Committee of the Privy Council, resort to the judges has become unnecessary when the opinions of the law officers, the normal guides of the government in matters of law, are deemed insufficient. In recent years, however, several parliamentary acts have permitted references to the High Court for advice [51 & 52 Vict. Stat., v. 25, c. 41 § 29 (1888); 10 & 11 Geo. v, c. 30 (1920)]. The judges have been unfriendly to such legislation. A recent attempt to extend this practise encountered the stubborn and successful opposition of the law lords [see *Parliamentary Debates*, 5th series, vol. lxx, 755, 795, 914 (1928)].

From the time of Edward I judges have been summoned to aid the House of Lords in both its judicial and its legislative capacities. With a notable exception [Duke of York's Case, Rot. Parl., 39 Henry VI, no. 12 (1460)], they have always attended on request, and at the time of the American Revolution it was well settled that they were bound to give advice on questions of law arising in cases before the house (Blackstone's *Commentaries*, vol. i, *168). But ever since the judicial functions of the House of Lords have been entrusted to the law lords, the opinions of the judges have been less and less frequently invoked. In recent times, also, the right of the House of Lords to ask the judges "what the law is, in order to better inform itself how, if at all, the law should be altered," has lain dormant, but as late as 1912 its existence was recognized [Attorney General for Ontario v. Attorney General for Dominion (1912) A. C. 571, 586]. While the judges have declined to answer questions because not "confined to the strict legal construction of existing acts of Parliament" [*In re The London and West-*

minster Bank, 2 Cl. & F. 191, 193 (1834); M'Naghten's Case, 10 Cl. & F. 200 (1843)], "the right to have the opinions of the Judges on abstract questions of existing law" was vigorously affirmed.

In the United States the advisory opinion did not follow its English history. The doctrine of the separation of powers, its basis and applications, as well as the unique scope of judicial review under American written constitutions, have always confined American judges, in the main, to adjudication. The framers of the constitution rejected the proposal to confer upon the executive and Congress the right to require opinions from the Supreme Court (Farrand. Max, *Records of the Federal Convention*, 3 vols., New Haven 1911, vol. ii, p. 341). When, therefore, President Washington in 1793 submitted to the justices of the Supreme Court twenty-nine questions (Sparks, Jared, *Writings of George Washington*, 12 vols., Boston 1834-38, vol. x (1836) append. xviii) concerning America's neutral rights in the Franco-British conflict, Chief Justice Jay and his associates politely but firmly refused to comply with the request. Jay argued that the constitutional provision enabling the president to call upon the heads of departments for advice precluded the possibility of requiring advisory opinions of the justices, and the giving of such opinions would not be a proper exercise of the "judicial power." The court has ever since rigorously abstained from such advisory opinions, even when elicited in the guise of formal litigation [see series of decisions from *Hayburn's Case*, 2 Dall. 409 (U. S. 1792) to *Muskrat v. United States*, 219 U. S. 346 (1911)]. It has based its repeated refusals to entertain other than actual litigation *inter partes* on its conceptions of the requirements of the separation of powers and the restriction of "judicial power" under the constitution to the disposition of "a case or controversy." Upon like considerations the High Court of Australia has excluded advisory opinions from the scope of "judicial power" under the Australian constitution, which is largely modeled upon that of the United States [see *Luna Park, Ltd. v. Commonwealth of Australia*, 32 Comm. L. R. 596 (1923)].

In most of the states the inability to resort to the courts or their judges for advisory opinions, on the part of either the executive or the legislature, is a firmly rooted doctrine of public law. So far as the advisory opinion has prevailed in American states, Massachusetts has set the ex-

ample. It was first introduced in the Massachusetts constitution of 1780 (pt. 2, c. 3, art. 2); the first opinion was given in 1781 [Opinions of the Justices (1781), 126 Mass. 547 (1879)], and it has survived two efforts to secure its repeal, in 1820 and again in 1853. This feature of the Massachusetts constitution was followed in the New Hampshire constitution of 1784 (now art. 74, of the constitution of 1902); in the Maine constitution of 1820 (art. 6, § 3); in the Rhode Island constitution of 1842 (art. x, § 3, reaffirmed in amendment xii, § 2, 1903); and is still maintained in these New England states. The practise was also adopted in the Florida constitution of 1868 (now art. iv, § 13), in the Colorado constitution of 1886 (art. vi, § 3) and in South Dakota in 1889 (art. v, § 13). Two states have sanctioned the advisory opinion by statute without explicit constitutional authority [see Alabama Civil Code, §§ 10290-91 (1923); Opinions of the Justices, 209 Ala. 593 (1923); and Revised Code of Delaware, c. 13, § 2, c. 110, § 11 (1915)]. But in several states there has been a recession in the use of the advisory opinion. The second Missouri constitution adopted the device in 1865 (art. vi, § 11), but it had an ineffective history and was abandoned by the constitutional revision of 1875. In Vermont the statute of 1864 authorized advisory opinions and was repealed in 1915, and in Minnesota such a statute was declared unconstitutional [Matter of Senate, 10 Minn. 78 (1865)]. In New York, North Carolina, Nebraska, Oklahoma and Pennsylvania advisory opinions were at first given without statutory authorization, but the practise has become atrophied. And in some of these states power to do so has been explicitly denied by the highest court [*Re Board of Public Lands*, 37 Neb. 425 (1893); *Matter of State Industrial Commission*, 224 N. Y. 13 (1918); Opinions of the Justices, 64 N. C. 785, 792 (1870)]. Likewise in Connecticut and Ohio the judges have refused to give opinions requested by their legislatures [Reply of the Judges, 33 Conn. 586 (1867); *State v. Baughman*, 38 Oh. St. 455 (1882.)]

In Canada the idea of the advisory opinion does not find itself in the grip of the doctrine of the separation of powers, nor is it involved in the unique scope of judicial review over legislation to which the American constitutional system gives rise. But even in Canada the use of the advisory opinion has encountered judicial opposition. Nevertheless it has won its way, so that at present the governor general or either

house of Parliament may require the opinion of the Supreme Court of Canada upon any question of law or fact concerning the constitutionality of any dominion or provincial legislation or on any other matter which the governor in council sees fit to submit [Revised Statutes of Canada 1927, c. 35, §§ 55-56; see *Attorney General for Ontario v. Attorney General for Canada* (1912), A. C. 571, 585-86]. Seven of the nine provinces have likewise adopted statutes requiring their respective courts to answer similar questions. In several of the Latin American countries there are provisions for legislative reference of legal questions to the courts and for the participation by the judges in legislation affecting the codes of these countries (Rodriguez, J. I., *American Constitutions*, 2 vols., Washington 1906-07, vol. i, p. 278, 313, 375, 415; vol. ii, p. 336-37).

The procedure for eliciting advisory opinions is relatively simple. The executive, by written request, or either house of the legislature by resolution, submits to judges a number of questions affecting a proposed measure or action. Answers are given by the judges collectively or *seriatim*. Even where the duty of giving such opinions is well established, the judges may refuse to express opinions, for they very often exercise the right to pass upon the reasonableness of the demand made upon them [*Interrogatories of the Senate*, 54 Colo. 166 (1913); *Answer of the Justices*, 148 Mass. 623 (1889); *Answers of the Justices*, 95 Maine 564 (1901); *Matter of Northern Missouri R. R.*, 51 Mo. 586 (1873)]. That the giving of advisory opinions by judges runs counter to the instinctive feeling of American lawyers is attested by the refinements to which courts have resorted in order to contract the scope of this duty. Thus, as a condition of giving advisory opinions, courts have required that no private rights be involved [Opinion of the Court, 62 N. H. 704 (1816), but see Opinion of the Justices, 190 Mass. 611 (1906)]; that no existing statutes be affected [*Re Penitentiary Commissioners*, 19 Colo. 409 (1894)]; that the question be *publica juris* and framed with sufficient definiteness; that no questions of fact be in issue [see *Dinan v. Swig*, 223 Mass. 516 (1916)]; and, usually, that the question be not of a nature affecting private interests [*Re Opinion of the Judges*, 43 S. D. 645, 647 (1920)]. Under the Canadian practise any question submitted is conclusively deemed to be appropriate for response. In all states, with

the exception of Colorado [Matter of Constitutionality of S. B. 65, 12 Colo. 466 (1889)], the opinions are those of the individual judges and are not given as the opinions of the court. Thus, legally, they are not binding in later litigation. But while the technical doctrine of *stare decisis* is not applicable, the views expressed in an advisory opinion not only receive careful consideration in subsequent litigation but in fact exercise a powerful influence psychologically upon adjudication [see Loring v. Young, 239 Mass. 349, 361 (1921)]. In Colorado such opinions have the authority of decisions.

The device, it is urged, permits the prompt resolution of legal doubts and avoids the waste of enacting legislation which the courts subsequently invalidate. But these conditions treat questions of law and constitutionality *in abstracto*, and fail to consider the practical implications of the American constitutional system. Constitutionality is not a fixed quality; in crucial cases it resolves itself into a judgment upon facts. Every tendency to deal with constitutional questions abstractly, to formulate them in terms of barren legal questions, leads to dialectics, to sterile conclusions unrelated to actualities. Legislation is largely empirical, based on probabilities, on hopes and fears and not on demonstration. To meet the intricate and subtle problems of modern industrialism, the legislature must have ample scope for putting its prophecies to the test of proof. To submit legislative proposals rather than the deliberate enactments of the legislature to judicial judgment is to submit legislative doubts instead of legislative convictions. The whole focus of the judicial vision thereby becomes altered. Legislation is thus deprived of its creative opportunities. For the history of modern legislation amply proves that facts may often be established in support of measures after enactment, although not in existence previously.

When actual cases come before them, courts profess not to exercise revisory powers over legislation, and there is an important truth in the theory. The whole milieu of giving advisory opinions on proposed bills or executive action is inevitably different from the process of adjudication in litigation which contests either legislation or the assertion of legislative authority. Judges have frequently deplored the lack of competent legal assistance and the inadequate opportunity for mature deliberation in rendering advisory opinions. While in a few states

judges may command the assistance of the attorney general or *amici curiae*, in practise the aid of counsel is rarely received. Experience has shown that whatever provision may be made on paper, advisory opinions are bound to move in an unreal atmosphere. In the attitude of court and counsel, in the availability of facts which underlie litigation, there is a wide gulf between opinions in advance of legislation or executive action, and decisions in litigation after such proposals are embodied into law or carried into execution. Moreover advisory opinions involve the judges too intimately in the process of policy and thereby weaken confidence in the disinterestedness of their judicatory functions. On the other hand advisory opinions weaken legislative and popular responsibility. It is not merely the right of the legislature to legislate and of the executive to act; it is their duty. Legislatures and executives may inform themselves as best they can; but the burden of decision ought not to be shifted to the tribunal whose task is the most delicate in our whole scheme of government, involving as it does the power to set limits to legislative and executive action within those vague bounds which are undefined and *a priori* undefinable. In these considerations we must find explanation for the judicial hostility to advisory opinions even where, as in England, there are no formal restrictions against them.

INTERNATIONAL. Disputing states have long been in the habit of inviting mediators, councils of conciliation or commissions of inquiry to advise them on a settlement. International organizations have frequently found it con-

venient to summon committees of jurists or to establish legal sections to advise them on legal problems. The pronouncements of such bodies might be called "advisory opinions."

The recommendations made by the Behring Sea, the North Atlantic Fisheries and other arbitral tribunals on certain points have some resemblance to advisory opinions, though motivated by considerations of expediency rather than of law. The term has, however, been confined in both national and international practise to opinions on disputes or questions of law not formally binding but issuing from a tribunal (or from its judges) with authority to give binding decisions.

Advisory opinions as a recognized international practise arose out of Article 14 of the League of Nations Covenant, which declared that the prospective Permanent Court of International Justice "may also give advisory opinions upon any dispute or question referred to it by the Council or by the Assembly." This provision seems to have originated in Lord Robert Cecil's draft covenant submitted to the Peace Conference on January 16, 1919, and was later supported by Larnaude, of France, after President Wilson's return to Paris. Modifications in the phraseology were suggested by David Hunter Miller, the American legal adviser, to exclude the possibility of compulsory jurisdiction developing under the clause, and by the drafting committee which changed the word "advice" to "advisory opinion," thus emphasizing the function's judicial character.

The commission of jurists which framed the court statute in the summer of 1920 provided that "questions" submitted for advisory opinion be considered by a special commission of the court with three to five members, while "disputes" so submitted be considered by the whole court "under the same conditions as if the case had been actually submitted to it for decision." There was disagreement, however, concerning this provision, and eventually the article in the draft statute dealing with advisory opinions was eliminated altogether. The judges of the court were thus confronted with the problem in drawing up their rules of procedure. Judge John Bassett Moore, of the United States, prepared a memorandum asserting that the giving of advisory opinions was not an "appropriate function of a court of justice," and might reduce the court's prestige and its opportunity to decide litigated cases. He concluded from the English text of the Covenant that the court

was at liberty' to decline to give an advisory opinion when requested, and advised against including any rules on the subject, leaving the court free to handle each application on its merits.

This, however, was not done, and rules were drawn closely assimilating the procedure to that in litigated cases. A proposal that advisory opinions might be given secretly was voted down eleven to one, and the revised rules of 1926 expressly provided for the reading of advisory opinions in open court. The rules, in conformity with the Covenant, provide for requests for advisory opinions only by the Council and Assembly of the League. In practise only the Council has made such requests, though it has sometimes acted upon the initiative of the international labor organization or of certain states. It has not been decided what vote is required in the Council for such a request, although apparently, when the request concerns a dispute before the Council, the votes of the disputants are not necessary.

The court's statute is an instrument independent of the Covenant and rendered operative by a signed and ratified protocol. It defines the court's jurisdiction as "comprising all cases which the parties refer to it and all matters specially provided for in Treaties and Conventions in force" (art. 36). The last phrase appears to furnish the legal basis for the court's recognition of the advisory jurisdiction mentioned in the Covenant, and it would seem to furnish equal basis for recognizing advisory jurisdiction conferred by any other treaty. Doubtless, however, the court could refuse to accept any expansion of its advisory jurisdiction. The opinion of Judge Moore that the court was not obliged to respond to requests, even from the League Council, was confirmed, but with a substantial dissent, in the Eastern Carelia case. This arose out of a dispute between Finland and Russia, placed by the former before the Council without the latter's consent. The court refused to give an opinion on request of the Council, holding that it could not "even in giving advisory opinions depart from the essential rules governing their activities as a court." This is in accord with the established principle of international law that "no state can without its consent be compelled to submit its disputes with other states . . . to any kind of pacific settlement." The court has also indicated that it would decline to answer questions which were wholly abstract or lacking in precision.

Fifteen advisory opinions have been given by the court (1928), most of them dealing with the legal aspects of disputes between states. Several have dealt with the organization and competence of international organizations, particularly the international labor organization, and a few have defined the jurisdiction of international judicial and quasi-judicial bodies. The opinions in the last class on the scope of the jurisdiction of the League Council as limited by the domestic jurisdiction clause ('Tunis Nationality decrees case) and on the limits of the court's own advisory jurisdiction (Eastern Carelia case) have been especially important for the development of international law.

A certain suspicion of advisory jurisdiction has been shown by several of the Americans who have had a hand in the development of the court, and by the United States Senate. The latter attached a reservation to its resolution of adherence to the court protocol, prohibiting the court from "entertaining any request for an advisory opinion touching any dispute or question in which the United States has or claims an interest." The unwillingness of the signatories of the court protocol to give the United States a veto on advisory opinions not enjoyed by any other state brought the matter to a deadlock. The fears that opinions might be based on inadequate argument, might prejudice the court's consideration of similar facts in subsequent litigation, might be ignored to the detriment of the court's prestige or might be given without consent and hearing of the real parties at interest, have not materialized. Nor has the court become involved in political controversies or lost its independence. The court has provided for the exercise of this jurisdiction in a way to render any such results extremely improbable.

Advisory opinions, although they do not render controversies formally *res adjudicata*, have in practise often served to settle international disputes and have been looked upon as sources of international law, equal in value to opinions in litigated cases. Like declaratory judgments they afford a means for authoritatively establishing legal points and thus preventing disputes from arising. They often make it possible for states to gain the advantage of judicial settlement for disputes which they would be unwilling to submit for decision. This is partly because requests for advisory opinions may be initiated by third states and made by the League Council without direct

responsibility of the litigants, and partly because advisory opinions are not formally binding. The advisory procedure, however, has the further merit that the legal can be separated from the political aspects of a controversy. Presence of the latter aspects frequently makes states unwilling to submit to arbitration or judicial decision, but often, with the legal aspects authoritatively decided and the facts clarified, the political problems prove to be readily soluble.

AEGIDIUS COLONNA (c. 1250-1316), mediæval political theorist. From early youth he was a member of the order of Augustinian Friars. He is said to have become tutor to the future Philip the Fair of France, and it was for Philip that he prepared his most famous work, *De regimine principum* (first published in Augsburg, 1473, written before 1285). A mediæval French version of this work was edited by S. P. Molenaer, under the title, *Li livres du gouvernement des rois* (New York 1889). In 1295 Aegidius became archbishop of Bourges, and took the side of the pope against Philip the Fair in his second important work, *De ecclesiastica potestate*.

The first work, which was very well known in the late Middle Ages, is interesting as representing very clearly the influence of St. Thomas Aquinas' rediscovery of Aristotle's *Politics*. To Aegidius, as to St. Thomas, the state is no longer an artificial institution devised to remedy the evil in human nature, but the natural form and method of human life and progress. But *De regimine principum* is even more significant as illustrating the first appearance of a doctrine which became of great importance

in the sixteenth and seventeenth centuries. This was the thesis that the king is above the law since he is himself its source, thus contradicting not only the view of Aristotle, but also the traditional principle of mediaeval society, that the king or ruler is subject to the law of the country.

In *De ecclesiastica potestate* Aegidius maintains in its most extreme form the doctrine of Pope Innocent IV and the other canonists of the later thirteenth century that all temporal as well as spiritual matters are in principle subject to the church and the pope. He holds, moreover, that no one can justly hold temporal powers unless he is spiritually regenerated by baptism and sacramentally absolved by the church. In this he contradicts the doctrine even of Innocent IV, as well as of Aquinas, that political authority is lawful and natural among unbelievers as well as among Christian men. Aegidius expressed similar views concerning property. All property, he says, is under the *dominium* of the church, and can be held only by the man who is baptized and absolved. Wycliffe, in *De dominio civili*, may have been influenced by this conception.

AEHRENTHAL, ALOIS LEXA, GRAF VON (1854-1912), Austrian diplomat and statesman. After a long apprenticeship as attaché and ambassador to Russia he became Austro-Hungarian foreign minister. Since he was known as an ardent supporter of close relations between the three imperial courts of Germany, Austria-Hungary and Russia, his subsequent steps against Russian interests in the Balkans came as a surprise. Aehrenthal, hoping to reestablish the prestige of the Dual Monarchy in international affairs, soon came into conflict with Izvolski, the Russian foreign minister, who was intent on making good the mistakes of the Japanese War and reviving the traditional Russian Near Eastern policy. The first clash came with the beginning of 1908 when Izvolski opposed Aehrenthal's plan for a railway through the Sanjak of Novi-Bazar, holding it to be an expression of the Austrian *Drang nach Osten* and a menace to the Slavic states of the Balkans.

Aehrenthal's name is associated chiefly with the crisis arising later in 1908 when Austria annexed the two Turkish provinces of Bosnia and Herzegovina, which had been occupied since 1878 under a mandate of the powers. At first, in the famous Buchlau interview between Aehrenthal and Izvolski, the latter gave his consent in exchange for Austrian approval of the opening of the Straits to Russian warships; but when the announcement of the annexation caused a storm in European chancelleries, Izvolski maintained that he had been deceived by Aehrenthal and came out in open opposition. The crisis dragged on through the winter of 1908-09, but war was finally averted. Austria was supported by Germany, Russia was in a state of military unpreparedness, and France and England were disinclined to go to war. Aehrenthal concluded a separate agreement with the Turks, and forced the intransigent Serbs to yield, after combatting the belligerent suggestions of Conrad von Hötzendorf, the Austrian chief of staff. The affair left Russo-Austrian relations exceedingly strained, and in a sense marked the beginning of the Near Eastern tension which ended in the World War.

AGAZZINI, MICHELE (1790-1840), Italian economist. Agazzini's best known and most important work, *La Science de l'économie politique, ou Principes de la formation, du progrès, et de la décadence de la richesse: et application de ces principes à l'administration économique des nations*, was issued in French (Paris 1822) and in Italian (Venice 1827). Later he published a critical essay on the theories of value of Smith,

Malthus and Say, *Sconvenevolezza delle teoriche del valore insegnate da Smith, dai professori Malthus e Say e dagli scrittori più celebri di pubblica economia* (Milan 1834).

The *Economie politique* is remarkable for certain original ideas. For example, he considers the concept of cost of reproduction and the effects of forecasts and errors in forecasting. The principles of economics he expounds first in a milieu of isolated men (*l'état sauvage*); next in a single market, with exchanges; then in a market with differentiation in occupational training and state intervention; finally in a market with foreign trade, customs and money.

RICCARDO BACHI

AGE SOCIETIES. Apart from social units based on the blood tie, such as the family or the clan, many primitive communities recognize "associations." These unite members irrespective of real or putative kinship, but with a view to a common status or common interests. Among units of this type age grades and age societies constitute a distinct category.

Since savages generally fail to keep account of their ages by years, it is only approximate coevals that are grouped together. Puberty forms a natural line of demarcation. Boys or girls are often advanced to the status of adults by a ritual roughly equivalent to confirmation, and those initiated at the same time constitute a definite company. Later they marry and pass into the grade of married folk or "elders." This tripartite division of society was regarded by Schurtz as naturally reflecting the conflict of adjoining age groups or generations, hence he considered the grades of the uninitiated, of initiated single men and of elders as potentially universal and as the earliest forms of age grading. Wherever grades were more numerous, he assumed that there had simply been a subsequent elaboration of this primitive scheme.

This last conclusion may be at once dismissed as *a priori* rationalism. Whenever there is a joint admission into a definite age grade, the coevals thus initiated frequently form a definite group for life; and the number of such companies depends solely on the local conditions regulating initiation rites. Thus the Masai of East Africa have indeed three status grades corresponding to Schurtz's threefold division, but neither the uninitiated boys nor the married men form definite units. On the other hand all those initiated within the same quadrennium are linked together as a lifelong company with

mutual obligations and claims. An age mate in this sense occupies his fellow member's hut and enjoys marital rights over his host's wife when he visits a strange village; and of these age companies there would be at any one time not three, but possibly eight or nine.

The distribution of age grades militates against the theory that they represent an essential development of human society. Thus even in Schurtz's map their complete absence in Siberia is significant, while Father Schmidt restricts the range to parts of Oceania, Indonesia, southern Asia, East Africa, the Bororo in South America and the Eskimo in North America. This is doubtless going too far, for there is clear evidence that West African Negroes share the institution. Thus the Ibo are divided into eight classes, each with distinctive duties: one has to clean towns and roads, another clears away trees and acts as guards, and so forth. Each grade forms a society into which boys enter, sometimes even long before puberty, although more generally at that period. Usually some such rite as circumcision or tooth-filing marks the entrance into the lowest class. A merging into a different type of association is noted by Talbot for Nigeria, inasmuch as wealthy people could pay fees and thereby skip some of the lower grades.

The Northern Plains Indians had a similar division of male society—sometimes with parallel series of women's associations—into age societies. Among the Blackfoot the "All Comrades" were responsible for the safety of the camp, while among the Arapaho a whole series were under the guidance of the old men's grade. In other tribes of the area there was less integration of the several component units, though the underlying pattern was clearly uniform for a particular people. Closer examination has shown, however, that the age factor is not truly comparable to that of other regions. The essential feature in the plains is purchase of a set of ceremonial privileges, and it is merely through the fact that the rights are bought jointly by groups of approximate coevals that a basic division into age societies is produced.

In another sense, however, the age factor is obviously conspicuous even here, for why should age mates buy membership together? Schurtz must be recognized as having put his finger on a true bond in linking individuals together. His error lies merely in insisting on the necessity for formal association of coevals,

which the geographical facts of distribution fail to support. A tendency toward union on these lines, whether it finds formal expression or not, can hardly be denied.

AGENCY, in Anglo-American law, covers the bulk of relations and transactions in which one person (agent) is dealing with another (third party) on behalf of still another (principal). It is concerned therefore with the external business relations of an economic group or unit and with the powers of the various representatives to affect the legal situation of the principal (person or organized group). In the internal set-up of either the business or the production unit, agency plays its part primarily in the organization process: every member in being hired, fired or promoted is for the moment an outsider with reference to the unit, and deals as an outsider with some representative. And of course the eternal problem of government, whether of the state or of any other unit, involves agency with internal organization in another way: to cope with unforeseen conditions it is repeatedly necessary to give representatives powers wider than those they are normally expected to use. Thus an agent's effective powers in dealing with outsiders often extend to transactions which he is under a duty to his principal not to enter into ("apparent authority"; "authority" alone, or "real authority" covering the case where power, and privilege as against the principal to exert the power, are coextensive).

It is obvious that some type of legal representation became needed increasingly as business units came to involve transactions conducted at a distance (as in the case of factors) or grew in size (the firm, the house, the corporation). The original models seem to have been the steward of a lord and the servant with a specific matter to attend to; the law was therefore long plagued with refined distinctions between "general" agents, the only ones with whom an outsider could deal with moderate safety (the steward model), and "special" agents, whose powers the

courts viewed very narrowly. With the persistent shift to larger business units with a running organization of subdivided powers, the law has become more realistic on the point. Compare, for example, the recognition, in the doctrines of ratification and adoption, of the practise by which a principal approves a transaction which he (it) had not previously authorized—even, at times, when entered into by a person who was not at the time his (its) agent at all. Yet the law still lags; especially, perhaps, in the field of marketing. The courts attempt to bring most of the marketing structure under one or the other of two legal concepts: agency (the "title" to goods being in the principal, there follows, for example, permissible control of resale prices and, in the event of the agent's bankruptcy, the recovery by the principal of the specific goods and outstanding accounts; by this concept the contracts of the agent within his powers obligate the principal only); and sale (the "title" to goods being in the "representative," who owes the price and is alone responsible on his contracts, it follows that no resale price maintenance is enforceable). These concepts are taken as sufficient between them and as mutually exclusive. But they rather obviously fail to describe or deal adequately with the complicated marketing structure involved, for example, in "consignments" with or without immediate invoicing on fixed terms; in exclusive "representation" in a given territory with or without agreements for taking minimum quantities; or in subsidiary marketing corporations (involving, for example, tax questions, when the internal billing of goods is built to deprive one or the other corporation of any taxable profit or stockholders' rights, when the parent corporation is being "milked").

The business term "agency"—i.e. "some intermediary in the distribution process"—is thus at wide variance with what the lawyer understands by the word. Agency in law is confined to the useful but somewhat antiquated legal framework of the business set-up. It gives legal validity to most deals made by representatives. It imposes certain minimum duties on the representatives (diligence, good faith, accounting), in one instance, indeed, going beyond the current practises among higher executives (the principal may at his option take over any deal in the line of the agent's business which the agent has made on his own, without permission). But the law of agency affords no safeguard against what chiefly interests the business man—stupidity or bad judgment. This accounts, to a

great extent, for the growing practise of large units using standardized printed forms to limit their minor agents' discretion, and to make salesmen's agreements subject to approval by the home office or credit department. And the law of agency is especially open to abuse where the "principal" is not organized for supervision, as in the case of an absentee whose affairs are conducted by a trusted adviser, or in the case of the larger corporations where management has been dissociated from investment.

Concepts grow out of specific typical fact situations and are slow to become systematized; it is therefore not surprising that the concept of legal representation developed differently in different times and places, and even within a single legal system. Thus, apart from the mercantile field, other types of representation developed in regard to decedent's estates (executors, administrators), trusts and governmental officers. Each of these classes, as also in the case of corporation directors, is the subject of peculiar rules, at times widely different from those applicable to agents in general. A thoroughgoing systematization of the law of representation at large has never been worked out in Anglo-American law. And the fact that on the continent totally divergent institutional divisions of the same subject matter work out, in both domestic and international business intercourse, with practical results so similar to ours, leads one to wonder how far the legal theory on the subject has great practical import.

Such a doubt, at least, is well founded as to the philosophy of representation. The struggles of legal philosophers to explain or justify representation have moved from an outworn premise to solve an unreal problem. They begin with some such assumption as that a man can acquire rights or obligations only by exercise of his own will or by personal participation in some transaction (our "privity of contract"); there is then the problem of carrying the acts of the representative back to the will or acts of the principal—e.g. by a fiction of identification or by inventing a delegation of will; and finally the problem of finding a concept for this purpose which squares with all the rules on the subject, or the set of related subjects, existing at any given time in one legal territory. But it saves labor to think of law as in the main a reflection of felt expectations and necessities, and to recognize that legal rights and obligations are acquired in the first instance through exercise of the will not of the parties but of legal officials.

Under such a view representation becomes normal in law because normal in life. This is not to deny importance to legal philosophy or legal theory. The view that a principal must be in existence to be "represented" still ordinarily annuls an agent's powers on the unknown death of his principal; the feeling that a contract is an abnormal relation and can affect at most the contracting parties is still potent in the law; only by turning to account the notion of agency was assignment of debts accomplished; even negotiable paper carries, in the obligatory formula words "order" or "bearer," the marks of its origin in an agency to collect. But a modern legal philosophy has as its task, in this field as in others, rather to examine the origin and working of ancient premises than to accept them as posing its problems. Nor does it serve much purpose to attempt a complete philosophic harmonization of a set of rules, where some are fossils from a past age and some are only in process of emergence.

On the whole, agency has been of almost equal importance with contract as a device facilitating the development of the modern business structure—in good part because of its high flexibility. It was once a, if not the, major way of organizing a mercantile enterprise, as in the relationship between the master of a vessel, the supercargo and the factor. It still remains the major building material, even in the corporate structure. It has, moreover, been a fertile matrix of specialized adjustments: the transfer of contract; the attorney-at-law (naturally one of the earliest forms recognized by lawyers); brokerage; the power to a mortgagee to foreclose by sale even after the mortgagor's death; and, quite recently, the suability of an unincorporated labor union. Finally, with growing specialization, agency takes on another aspect, especially in the purveying of services; the specialized purveyor (as in bank handling of collections and stock brokerage) moves largely out of the control of his principal, becomes an independent unit and may gather sufficient financial power to finance and even control his scattered "principals" (so the textile factors and import bankers), or may by reason of distance and the manipulative opportunities of a central market call forth legislative control in the interest of his unorganized principals (so the produce commission men). In all such cases of independence of the "agent" the tendency is strong for the one-time agency to become swallowed up in contract, as between two independent dealers (railroads. warehouse-

men, stock brokers). In such cases the control of the specific operations passes increasingly out of the "principal," and the "agent" makes any necessary contracts or arrangements on his own account. In the grain elevator case the "agent" will not even be required to redeliver the same grain he received; in the case of a bank transmitting funds the money received goes into the bank's general assets, and only a pure contract relationship remains. On the production side, where the relationship as for example between "master" and "servant" is of a slightly different character since the "servant" does things for his "master," as contrasted with an agent who deals with people for his principal, there is a similar development toward a contractual arrangement; thus the master—or principal—is freed from responsibility for wrongs committed by the "independent contractor" in the course of getting the agreed job done.

AGENT PROVOCATEUR. *See* ESPIONAGE.

AGGRESSION, INTERNATIONAL. Aggression, aggressive war and aggressor nation have become familiar terms during and since the World War. Before then the word "aggressive" was occasionally used as synonymous with "offensive" in describing and condemning certain kinds of war. The expression "offensive war" has fallen into disuse, and "aggressive war" is now often used as the antithesis of "defensive war." "Aggression" became the subject of renewed interest through the stipulation of the Versailles Treaty requiring Germany to make reparation "for all damage done to the civilian population of the Allies and their property by the aggression of Germany," and through the language employed in Article 10 of the League Covenant (1919) wherein "the members of the League undertake to respect

and preserve as against external aggression the territorial integrity and existing political independence of all members of the League." The Treaty of Mutual Assistance (1923) contributed the provision that "aggressive war is an international crime," etc. This phrase reappeared in the American Revision of the Treaty (1924) and in the subsequent Geneva Protocol of September 1924. In both the American Revision and the Protocol an attempt was made to base the definition of an "aggressor nation" on refusal of arbitration, whereby the crime of aggression might be better identified. All three proposals were designed to bolster up the sanctions of force contemplated by the Covenant, but were rejected by the League.

The inherent difficulty and danger of defining aggression was one of the reasons for rejection. The wisdom of this action is supported by the analogy between aggression and fraud. The courts, including English and American, have consistently refused to define "fraud" but will decide what constitutes fraud from the facts in each case. Manifestly it is much harder to set limits by definition to what constitutes aggression, because the conditions out of which war arises are far more complicated and elusive than in an individual case of fraud. But the principle is the same. Public opinion should be as free to pass upon aggression as courts are to determine fraud.

Notwithstanding the rejection of the Geneva Protocol, efforts have since been made to confine the outlawing of war to aggressive war. Such an effort was made by resolution in the United States Senate in the session of 1927-28, but failed. The issue was set at rest by the notes exchanged by the American Secretary of State with other governments, which led to the making of the Peace Pact, and by assent of the signatories definitely ruled out the qualifying word "aggressor." In his note of February 27, 1928, to the French ambassador, Secretary Kellogg said: "If, however, such a declaration were accompanied by definitions of the word 'aggressor' and by exceptions and qualifications stipulating when nations would be justified in going to war, its effect would be very greatly weakened and its positive value as a guaranty of peace virtually destroyed. . . . The Government of the United States desires to see the institution of war abolished." And again Secretary Kellogg, after discussing arbitration treaties, said: "We know of but one other form of treaty which can be concluded for the purpose of preventing war

and that is a treaty in which the parties specifically bind themselves not to resort to war. It is this kind of treaty which people have in mind when they discuss treaties for outlawing war, and it is a novel idea in modern international relations."

The universal acceptance of this Peace Pact will make it basic international law. Thereupon it will become unlawful and criminal for any nation to attempt to settle any dispute by force. But so long as war is recognized as lawful and legitimate, the question of "aggression" is irrelevant and the term "aggressor nation" will continue to be merely the epithet which each belligerent nation in self-righteousness hurls at its enemy. If a nation has the legal right, as it always has had, to seek and compel by force the settlement of its controversy with another nation, it is immaterial, except for purposes of public sympathy, which nation strikes the first blow or provokes the first blow to be struck. Under international law hitherto any nation has had the undisputed right thus to resort to war, and be strictly within its legal prerogative. Whatever immediate public opinion or historians later may say about an alleged aggressor nation, the war itself, its legality, its conduct, its destructiveness, its cruelties, are unaffected. Civilization is far more vitally interested in protecting itself against the devastation of war than in determining the intricate question of precise war guilt, that is, of international aggression. The question is thus purely academic except with regard to the theory of sanctions or legalized force.

Used in euphemistic contrast to "aggressive wars" considerable confusion has arisen over so-called "wars of self-defense." But the claim of "defensive war" has too often been invoked as a subterfuge for the "aggressive" use of force. The question of the bona fide exercise of the right of self-defense is placed in the hands of the people by the Pact. Therefore the decision between aggression and the legitimate right of self-defense is lodged with the people. If needed, public opinion may be aided in its decision by clothing the international courts with jurisdiction to hear the facts and determine the questions on the charge of a breach of the Pact. All such hearings should be open to the public and the press, but the court should have no power of enforcement, as this would savor of a super-state. Judicial investigation and publicity would enable public opinion to function more intelligently and effectively. But with war outlawed

and thus with every presumption against a nation resorting to force, public opinion may alone furnish a safeguard of the highest order.

AGIA, MIGUEL DE, Spanish missionary of the sixteenth century. He served on the colonial missions, particularly in Peru and in Mexico, where in 1563 he became professor of theology. He was considered an authority on the Indians, and was frequently consulted by the Viceroy of Peru and the Council of the Indies. He held the treatment of the Indians to be a social, rather than a political or economic problem. Although he believed they were unfit to be placed on an equal footing with the Spaniards, he thought they should find their place in the social scheme of the New World, and he taught their share in its development. The Indians, he maintained, were free men, but the king could justly compel their services for the necessary works of civilization, such as agricultural labor, construction of public works, labor in the mines, the tribute and domestic services for the *encomenderos*. Only in this way could they be taught to overcome their aversion to work beyond the production of bare necessities, and to feel that they were contributing to the progress of civilization. He demanded that the Indians should receive a just compensation for their services, and be assigned to work suitable to their state, with the opportunity of seeking other work to which they might personally be more inclined. He subscribed to Sir Thomas More's division of the day into six hours for work, eight hours for sleep or rest, and ten hours for one's own personal pursuits.

AGIO, with reference to the exchange of coins or currencies, is the difference between the values of two coins or currencies supposed normally to be equal in value. However, variations within the "gold points" of gold standard currencies are not usually subsumed under this term. Agio develops out of changes in the conditions of supply and demand of the currencies in question from those previously considered normal. After the appearance of an agio, produced by a shifting in the reciprocal demands of nations for each other's products or by changes in the quantities or qualities of the currencies in circulation, it is modified by speculation, which tends either to increase the agio or to restore equilibrium. The course of the German mark between 1915 and 1923 offers a good example. As long as the dealers thought that the mark might be revalorized, speculative buyers and sellers alternately predominated in the market. But in 1923, when all such hopes vanished, people sold marks without restraint and the agio on foreign money increased without limit. This explanation takes no account of adjustments through changes in the balance of payments, which always strengthen the tendency toward equilibrium.

The "self-inflamatory" tendency first becomes a real force in the market when, in addition to the regular dealers, the general public begins to speculate, and it is further strengthened by the substitution of other money for the depreciated legal tender in business transactions. A most important form of speculation due to agio is the purchase of foreign securities or money as a safer store of values. Just as this search for a safe store of values led people to hoard foreign coins and bullion in mediaeval times, so in modern times it causes international movements of capital during periods of monetary disturbance.

Speculation in coins before the establishment of stable currencies under the control of central governments was a common practise, because the frequency of changes in minting standards, the multiplicity of currencies in circulation, the existence of differences even among individual coins and the use of changing "ideal"

standards of value perpetuated a system of interrelated agios. Speculation in coins was further increased, as late as the seventeenth century, by the practise of concealing interest charges through an adverse exchange rate.

In the long run agios are always limited by the real values of the currencies or coins concerned, and any explanation of continuous depreciation in terms of speculation or of "lack of confidence" without reference to progressive inflation is necessarily false.

AGITATION. The word agitation is variously employed to mean a phase of a social movement and to specify a method of collective influencing. Conceived as a method, there is no consensus in distinguishing it from propaganda, non-violent coercion and kindred concepts. To avoid confusion the term is here taken to refer to that phase of a social movement which is characterized by the spontaneity with which a collective ideology is propagated and accepted. A social movement arises when common emotional dispositions find expression in a new system of symbols which condemns things as they are and prescribes what they ought to become. A social movement is consummated and reaches the phase of organization when it has passed through this agitational period and produced rather permanent alterations in the practises of society. Democratic, labor and nationalist agitations have figured most conspicuously in recent history.

When individuals are thrown into circumstances in which their claims on society are threatened or thwarted, they may identify themselves with one another and demand collective justice. Identification does not necessarily arise, however, and a man thrown out of employment may regard it as a purely private

affair with his employer. Identification is a process by which affections are guided by perceptions of similarity. Emotional relations within a large group become possible by interlocking identifications among those in visible contact, and by the sharing of symbols of the whole.

Society witnesses the competition of old and new ideologies for the allegiance of the dissatisfied. An agitation appears when many of the malcontents in a community are excitedly considering a new ideology as the symbol of their protests and demands. A satisfactory symbol system is a compromise formation in which the diverse affective drives of the discontented find expression. Since one of the wants of man is the justification of the rest of his wants, a demand for bread or ballots must be buttressed by a demand for justice. The appeal for justice is an appeal from one authority to another, and the laws of God or Nature or Historical Necessity may be invoked against the laws of man. The defiance of authority is associated with feelings of guilt and a desire for expiatory punishment, and protest ideologies gratify this craving to do penance by stressing the sacrifices necessary to reach the promised land.

In the agitational phase of social action men are willing to die for their convictions, and to forsake family and dependents in the service of the cause. Sectarianism thrives, and the true believers hesitate to mingle socially with the unbelievers, cultivating distinctions of vocabulary, dress and decorum. This is the era of prophets, apostles, heroes, martyrs and saints. Persistent persecution from the authorities provokes conspirative tactics and possible violence. On the whole the spreading of the new gospel proceeds with a minimum of tactical premeditation and with a maximum of joy in sharing a new revelation.

The transition from agitation to organization tends to occur even though society has made few of the concessions demanded. The tactician substitutes for the prophet, and the bureaucrat for the enthusiast; religion becomes magic, and ideology becomes phraseology. Sectarianism diminishes, and points of dogma and method become debatable, thus permitting the existence of a public opinion within the group and within the community of which the group is a part.

One function of agitation is to organize social energy for social change. But it may produce no substantial alteration in society, and serve entirely as a formation by means of which the

impaired self-feeling of a group is compensated. It is symptomatic of deep lying difficulties in adapting human impulses to a given set of cultural conditions, and it also implies a long antecedent process during which authoritative symbols have been de-valued.

AGOBARD (c. 779-840), archbishop of Lyons. Contemporary with Hrabanus Maurus and overlapping in youth the life of Alcuin and in old age that of Hincmar, he participated with this earliest group of mediaeval publicists not only in developing the claims of the church but also in producing that conjunction of classical political forms with barbarian social and political institutions, attitudes and customs which remains the base of modern political theory. He was not a systematic writer, and his literary remains are in the form of short dissertations and letters. He accepted the patristic view that since men were naturally equal, only sin justified slavery. He protested therefore against the denial of baptism to slaves without the master's consent, arguing that the inner man was subject only to God. He maintained firmly the authority of the church even over princes: the sacred canons of the church, "confirmed by the spirit of God, by the assent of the entire world, by the obedience of princes, by the agreement of the Scriptures," held for all men alike, and to act against them was to act against God and His universal church. The most remarkable quality of Agobard's thought was his detachment from some of the characteristic beliefs and institutions of his day, such as witchcraft, magic, trial by ordeal, and the worship of images.

AGOULT, CHARLES D' (1747-1824), French writer on political and financial subjects. He was made bishop of Pamiers (France) in 1787, emigrated at the beginning of the revolution and returned to France in 1801 after having renounced his bishopric. Later he refused the portfolio of minister of finance, offered him by Louis XVIII.

Strongly influenced by Montesquieu and Burke, he declared himself against popular sovereignty and in favor of the ideas of the historical school. However, he advocated a limited form of constitutional monarchy (*Lettres à un Jacobin, ou Réflexions politiques sur la constitution d'Angleterre et la charte royale*, Paris 1815). His more original work is revealed in his financial pamphlets, although even in this field he profited by neomercantilist doctrines

and by the experiences of Law and of the Bank of England. In 1815 he resumed work on a *Projet d'une banque nationale* (Paris 1815) which he had already proposed to Louis XVI at the beginning of the revolution as a means of gradually reabsorbing the *assignats* (q.v.). In his *Eclaircissement sur le projet d'une banque nationale* (Paris 1816) he energetically denounced the lack of specie from which France was suffering and the necessity of providing for it by issuing paper money based on a mortgage on the land, to be payable in ten years. He expected that in order to satisfy the needs of industry and trade a considerable part of this credit currency would continue to circulate even after the decade had elapsed. To insure the service of the debt thus contracted, d'Agoult proposed to replace the direct tax, especially the direct land tax, by consumption taxes. In his opinion a system of taxes on expenditure rather than on income would possess all the essential merits of equity, convenience and fiscal productivity (*Des impôts indirects et des droits de consommation*, Paris 1817).

I. INTRODUCTION. Throughout the history of civilization town and country have presented contrasts, not easily definable, in ways of living, in manners and morals, in conceptions of fundamental values. In static social periods these contrasts manifest themselves in social and economic friction having no significant political consequences. Until very recent times the manners and speech and dress of the countryman made of him a butt of ridicule for the towns-

man. Until recently, also, the prevailing rural view of the townsmen was that they were idle wasters, sharpers, parasites upon the husbandman's honest toil. In the exchange of products or services between town and country there were much bickering and incessant complaints of trickery. The townsman was most frequently accused of charging exorbitant prices, the countryman, of putting his best apples at the top of the barrel or selling in the town products

of dubious history, like contaminated cream or diseased meat. A solidarity of opinion condoned the vices of the one side and exaggerated the vices of the other, emphasized the virtues of the one and reflected doubt upon the virtues of the other. Town and country represented antagonistic cultures, each so tenacious of its own ways that language and manners often drifted far apart, as in the remotely analogous case of nation building.

In the last three quarters of a century compulsory education, by imposing universal standards of speech, has worked powerfully toward the obscuring of the cultural divergencies of town and country. Universal military service has exerted a similar influence in continental Europe. Above all, the modern economic process, with its easy transportation penetrating even the remotest rural districts, its standardization of consumption, of manners, speech, ideas might seem destined to obliterate altogether the lines between town and country. In fact, however, the lines of cleavage cut deeper than the superficial cultural manifestations. So long as the countryman faces nature directly, engaged directly in the work of production, while the townsman meets nature through the intermediation of "business," the distinction between country and city may be expected to persist. When agriculture becomes essentially capitalistic, as in some parts of the United States and other countries of extensive land resources, or in the plantation zones of the tropics, the contrast of country and town disappears and the class struggle assumes a form analogous to the class struggle in industry.

Within the country society as within the towns, conflict of classes may emerge: small proprietors against large, tenants against landlords, hired laborers against owners of estates. These conflicts contrast sharply with the general conflict between town and country interests which characterizes a true agrarian movement. In some instances, it is true, what appears to be merely a struggle between different rural elements is essentially an agrarian-urban conflict. Thus an anti-landlord movement wears a true agrarian character when the landlords as a class are absentees or, if not absentees, nevertheless assimilated to urban life. The owners of the *latifundia*, to whom tradition ascribes the ruin of ancient Rome, lived in the cities, leaving their estates to the management of *villici*. In the ancient regime of France the

large landowners were urbanized in culture; many of them lived continuously in Paris or in provincial cities. The Irish landlord of the eighteenth and nineteenth centuries spent most of his time in commercial and industrial England.

Genuine rural class struggles have no strict relevance in a study of agrarian movements. In any historical discussion, however, it is inexpedient to draw lines too sharply. Interclass rural conflicts, agrarian problems as viewed by the statesman, and self-conscious agrarian movements, while easily distinguishable in theory, form in history a closely woven texture which is difficult and profitless to unravel. In the sections that follow the subject is treated broadly, in order to cover the related group of rural problems popularly described as agrarian.

True agrarian movements have arisen whenever urban interests have encroached, in fact or in seeming, upon vital rural interests. Such encroachment may take the form of the absorption of the better agricultural lands by urban wealth, through violence as in Ireland, legal chicanery as in nineteenth century Mexico, the superior bargaining power of groups trained in trade, or by a combination of all three, as in England of the seventeenth and eighteenth centuries. Often such encroachment is of long standing, apparently accepted throughout generations. In such cases the emergence of an agrarian movement appears like a revolutionary infection, instead of the natural expression of agrarian ideals and sentiments. An instance is the widespread movement against the large landholders of eastern Europe in the late nineteenth and early twentieth centuries. Although the immediate cause of these movements was the distress which resulted from land reforms, it is improbable that the peasant had ever, in fact, accepted willingly his tributary position.

Another point at which the vital interests of the country have come into conflict with town or city centers is money lending. Especially in pre-capitalistic societies the loan contract has run in terms disadvantageous to the cultivator of the soil. He has been prone to borrow at usurious rates, being untrained to calculate properly the actual burden of the interest or his ability to repay. Whole communities have thus come to be saddled with debt, and have developed a common hatred of the money lender and the town society which he repre-

sents. This hatred becomes all the more violent when racial, national or sectional differences add weight to the social-cultural differences of country and town. Agrarian rage against usury provided a sinister background upon which religious and political fanaticism inscribed the vengeance of Kurdish shepherd and Turkish peasant against the Armenians. Antagonism to the alien British money lender was abundantly in evidence in the inchoate agrarianism of the American South in the early decades of independence. "Eastern Capital" was a bugaboo of mid-western agrarianism of the greenback and Farmers Alliance period.

A third point at which the conflict of urban and rural interests gives rise to agrarian movements is the distribution of the burden of taxation. Before the American Civil War the agricultural South was violently opposed to the tariff, holding it to be a means of taxing the South for the benefit of northern industry. The principal issue in modern agrarian movements, however, is that of prices. With the progress of the commercial and industrial system the country districts fall away from their primitive self-sufficiency and come to depend more and more upon a general market for the disposal of their products and the procuring of necessities of consumption and production. This occurs first of all in such staples as tobacco and cotton, where direct consumption is negligible. With improvements in production the range of commercialized agricultural production extends, until virtually the whole product of extensive farming districts finds its way to the market. The matter of prices becomes vital to the life of the rural community.

In the circumstances agrarian sentiment fastens itself now upon one feature of the commercial system, now upon another. The most general features of attack are the "middleman," who makes his profit, according to prevailing rural opinion, by depressing the price to the farmer and raising it to the urban consumer; the speculator, who emphasizes the spread of prices; the transportation agency, which takes, it is assumed, an exorbitant share of the product in return for carrying it to market. Similarly the middleman is charged with an unconscionable inflation of the prices the farmer has to pay for his supplies.

Out of this antagonism to the agencies of trade and transportation has arisen an agrarianism throughout western civilization which seeks to arm itself with either political or economic

weapons, or both. On the political side there is a ceaseless agitation, sometimes more or less successful, for the restriction of speculation, the control of railway rates, elevator charges, and the like. On the economic side there is a movement toward cooperative organization in the sale of products and the purchase of supplies. American agrarianism has been mainly political. The European agrarian movement has won its chief victories through cooperation, although it has also availed itself of political means, as in Denmark, where agriculture is not only thoroughly organized cooperatively, but also has bent the resources of the state to its ends in the control of railway rates, in taxation and in the provision of cheap credit for the establishment of farm ownership.

On occasion agrarianism has struck out against more abstract forces, like the appreciation in the value of money and the consequent fall of prices that attended the resumption of specie payments after the Civil War; the worldwide rise in the value of gold in the quarter of a century from 1870 to 1895; the credit deflation after the World War. While the greenback, free-silver and antideflation movements were not exclusively agrarian, they drew their chief strength from agrarianism.

Since the time of Colbert agrarianism has frequently fixed its chief interest upon tariff policies. During the eighteenth century the agricultural interest succeeded in fixing on the statute books of England a succession of laws designed to check the importation and facilitate the profitable exportation of corn. Especially since the middle of the nineteenth century, when the competition of the virgin lands of the American West began to make itself felt severely, European agrarianism has been decidedly protectionist. Agricultural duties have been a primary demand of the agrarians in all western Europe. In the United States the general agrarian approval of protection as a means of creating a domestic market was supplemented, in the period following the Great War, by a demand for direct protection, to be made effective through what amounted to an export bounty.

Varying as is the content of agrarian demands in differing circumstances, certain characteristics appear to be fairly general. However definite its material objectives, agrarian agitation promptly assumes a moral color. A semi-mystical sense of the paramount importance to humanity of agricultural production is every-

where manifest. Hence an agrarian movement under way is almost always characterized by violence of thought, and often violence of action. In spite of this interpolation of moral attitudes—or perhaps because of it—most agrarian movements are short lived. The emotions burn themselves out, leaving an aftermath of negativism and discouragement. Even at the present time, with agriculture extensively commercialized, there is the sharpest contrast between the ebb and flow of agrarian sentiment and the remorseless pursuit of political interests characterizing industrialism.

Most agrarian movements in history have been confined to areas limited relatively to the political system within which they have operated. This fact has most frequently foredoomed them to failure. When they have attained to partial success, the explanation commonly lies in the fact that non-agricultural forces have been enlisted to give dramatic coherence and cogency to agrarian demands, as in the case of the French physiocrats or the lawyers of the old South. Or else agrarian demands have been taken over by statesmen as essentially in the general interest. Thus agricultural protection in countries like France and Germany won the effective support of statesmen in the interest of national self-sufficiency in peace and war.

Agrarian movements are often bracketed with the labor movement in its various forms—trade unionism, social democracy—as parallel manifestations of the democratic movement of the times. On the whole, however, the contrasts between the two movements appear more marked than the analogies. The typical laborer owns little besides his hands; the typical member of an agrarian movement owns land and home, or at least holds a quasi-permanent tenure. The economic status of participants in the labor movement is roughly the same: in agrarian movements the rich farmer and the poor stand shoulder to shoulder. The conception of self-sufficiency has never been lost by the farmer; it has never been cherished by the laborer. The objective of the labor movement is simple and intelligible—to secure higher wages for shortened hours of toil. The agrarian objectives are abstract, undefinable, elusive. When the laborer has won in a struggle with the employer he carries away his winnings in his pocket. When the farmer has secured a law against usury or speculation, the probabilities are that usury and speculation change

their masks and come back into the market place. The labor movement admits of close and tenacious organization, capable of persisting through generations. An agrarian movement is held together by a moral fervor that cools.

Attempts have been made in various times to unite the agrarian and the labor movement for both economic and political ends, but the most extensive experiment in this direction, the composite peasants' and workers' government of Soviet Russia, has involved endless friction. In America the Knights of Labor, the Farmers Alliance, the Farmer-Labor party, have attempted to effect consolidation of agrarian and labor interests for the advancement of political policies. The permanent results of such combinations have not been notable.

In the following sections of this article the agrarian movements of the several periods of history and the several modern states have been traced upon the institutional background. No attempt has been made to attain to comprehensiveness, since a comprehensive history of agrarian movements in all their forms would represent a major section of the history of human culture. Neither has any attempt been made to establish a schematic unity, since unity would necessarily be misleading in the handling of such varying material. The more significant facts have, however, been assembled, to make possible a conspectus of the agrarian factor in its relation to social-political institutional development.

ALVIN JOHNSON

II. CLASSICAL ANTIQUITY. *Greece.* In ancient Greece, as in all primitive societies, the problem of land distribution was primary, and throughout Greek history formed the basis of all agrarian disturbances. For a long time cultivation of the soil, if not the only form of economic activity, surpassed all others in importance. At the same time the land was limited in extent, mountainous and unfruitful, and it was inevitable that struggles for its possession should develop among cities as well as between classes. Indeed these struggles, more than any other single problem, dominated the history of Athens, Sparta, Corinth and most of the other Greek cities.

In the earliest period of which we have record land ownership was vested in "families." But in those times the family, with its chieftain and numerous membership, resembled a minia-

ture people. Several of these families in each section of the country controlled the land. A family group gathered about it clients, actually serfs, who worked in exchange for protection, shelter and subsistence. The few slaves were a minor element in the situation, for slavery did not develop on a large scale until later, as a result of war and piracy, criminal conviction and non-payment of debts. The outlines of this early society are drawn for us in the *Odyssey*.

In the eighth century the older organization was superseded by one in which the aristocracy rose to power at the expense of the kings. The laws of Lycurgus in Sparta marked this change. During this period the aristocracy in each city was a minority group, composed of large landholders; at Epidaurus, for instance, one hundred and eighty men constituted the body politic, while still fewer held power at Heraclea, Cnidus or Thera. This first revolution, however, was followed by another in which undivided estates and that right of primogeniture which had formed the foundation of family organization were abolished. Thus the patriarchal family broke up into smaller groups.

At the same time the clients were struggling to improve their condition. They demanded freedom from their bondage to the family and from their obligation to surrender to it the entire yield of their labor. After innumerable conflicts, extending over many years, they achieved a degree of independence in which the master received only a part of what the client extracted from the soil. But that part the client still considered too large, especially as it was arbitrarily fixed, and he was constantly threatened with slavery in case of failure to discharge his obligations. So for four or five generations he fought sturdily for complete emancipation.

In Athens the men of the upland (*Diacrieis*) gained their freedom earlier than the men of the plain (*Pedieis*). The importance of the laws of Solon (sixth century B.C.) lay in the modification of property rights which they effected in Athens. Thereafter the debtor, when a free man, could no longer be enslaved for debt, for his liability was limited. In effect the land became free. "Those who, on this earth, suffered cruel servitude and trembled before a master, them have I set free," said Solon. But Athens was not all Greece and even at Athens complete equality was not achieved.

Sparta's policy was as peculiar in the agrarian

domain as it was in all others. No society was a more complete hierarchy, and if equality existed it was only in a very narrow ruling class. The ideas that Lycurgus had imposed on his few followers who conquered Laconia and Messenia were relatively simple. The aristocracy was like an army encamped on the land; it possessed lands that were inalienable, transmitted from first-born to first-born; 250,000 helots or serfs and 100,000 free men worked for it. The helots were really slaves of the state; they cultivated the land under condition of payment of a fixed sum to the owner, and it was by their labor that he and his family were maintained. Some tribute, too, came from the free men who lived near the borders of the state. One can easily understand that the Spartans lived in constant fear of helot insurrections.

Throughout the classical period, there was in all Greek cities a clear tendency toward concentration of property; and this concentration resulted in a proportionate increase in the number of slaves. In order to avoid disturbances the cities at this time encouraged their surplus landless citizens to colonize Sicily, southern Italy and regions along the Black Sea, or in Thrace. However, although concentration of land in large holdings occurred throughout Laconia, in Attica small holdings continued to exist for many years, and one still found there the small landowner or *thetes* who harvested less than 104 hectoliters of grain and less than 78 of wine or of oil. It was not until the destruction of vineyards and olive orchards during the Peloponnesian wars and the subsequent sales of land by needy debtors that land concentration began in Attica as well.

In the Greek cities where only a small portion of the population owned property either in law or in fact, it is not surprising that the dissolution of the great families should have been the signal for war between rich and poor. In the fifth century B.C. this struggle was everywhere at its height. The insistent demands of the poor for the cancellation of debts and the distribution of lands were the source of the long succession of riots and revolutions, lasting until the Roman conquest, which so facilitated the subjugation of Greece. At Megara and at Samos the property of wealthy families was confiscated and distributed. After the death of the tyrant Dionysius a general redistribution took place at Syracuse. At Messina the landed aristocracy was despoiled. From time to time the people set up dictatorships or tyrannies

which overthrew the existing systems of land ownership—dictatorships such as those of Aristodemus at Cumae, Nicocles at Sicyon and Aristomachus at Argos. Notwithstanding the silence which marks its internal history, Sparta, according to Thucydides, was well acquainted with revolutions of this kind. In the fifth century King Agis proclaimed the distribution of the lands of the plutocrats and was assassinated. Two hundred years later, Cleomenes attempted to achieve a similar reform throughout the Peloponnesus; but at his death this movement also was crushed. Within a short time another popular leader, Nabis, gained power, and likewise decreed a redistribution of land in the Peloponnesus. He was opposed by the aristocratic Achaean League, which appealed to Rome, and Nabis, like his predecessors, was assassinated. Thus to the very end agrarian conflicts dominated the history of free Greece.

PAUL LOUIS

See: SLAVERY; DEBTORS, RELIEF OF.

Rome. The history of agrarian evolution and of agrarian movements in Rome resembles that of Greece in its main outlines. In the early years the land was held without subdivision by the great families, or *gentes*, who cultivated it with the help of their clients, serfs attached to the soil. Somewhat later subdivision of property occurred; but while the great noble families enjoyed quiritarian ownership and full property rights, the plebs held only a precarious title to their small parcels of land. Roman territory, and consequently available land, was limited in this early period. There was as yet no need for many slaves; Dionysius of Halicarnassus mentions only 17,000 in 476 B.C. In succeeding years, however, this slave population was augmented by war, by convictions for crime and by the enslavement of insolvent debtors, and slave revolts broke out in 501, 498, 497 and 419 B.C.

Up to this time most owners had cultivated their own land. The leaders of the *gentes* followed the plow themselves and but few of them lived in the city. Holdings were relatively small; in the sixth century, when there were approximately 8000 quiritarian proprietors and 8000 tenants at will, five hectares was a large holding, and one fourth of a hectare was average size. But the extension of Roman conquests resulted in the formation of the *ager publicus*, a public domain, and these lands the patricians attempted to appropriate. Servius made an ini-

tial distribution of the land which satisfied the poor, but in the sixth and fifth centuries the nobles renewed the struggle and gained possession of the *ager*. Indeed they no longer paid even the rent charges which theoretically devolved upon them.

The fourth century marked the appearance of very large holdings. The war with Carthage had enriched the patricians and ruined the rest of the population, and numbers of small holders were obliged to sell their land in order to pay their debts. Most of these small holders became share tenants. The formation of these large estates alarmed conservatives who feared popular insurrections and dreaded the passions of a floating populace unattached to the soil. It was to save the state from such dangers that Spurius Cassius (consul 486 B.C.) had demanded a new distribution of the *ager*. Throughout the next two centuries one such agrarian project succeeded another. Icilius distributed acreage on the Aventine among the poor; in 366 the Licinian laws reduced the maximum of *ager* that a citizen might hold to 125 hectares, limited the number of cattle that one individual might graze on the *ager* and promised a redistribution of land to benefit all citizens. But these laws, too, remained futile.

Then followed the period of the great conquests and the struggle between the classes, patricians and plebeians, became intensified. By 46 B.C. the territory of the Roman Empire was more than a hundred times greater than it had been in 264 B.C. The patricians were exploiting veritable latifundia, with armies of slaves. In 190 B.C. Italian agriculture employed a million and a half slaves, who from time to time throughout the succeeding century were involved in formidable revolts (198, 196, 185, 140 B.C.). As Sallust said, conquest had ruined the poor. The small landholders were continually compelled to sell their holdings, for the conquered countries provisioned Italy at low prices. Expropriations became increasingly brutal. Plutarch tells us that the free peasant disappeared in the second century.

It was during this period that the Gracchi rose to power. Were they revolutionaries? They tried to subdue the agrarian plutocracy and to restore the old order of society, based on a more equal distribution of the land. In 133 B.C. Tiberius Gracchus again put into force the Licinian laws limiting occupation of the *ager* and providing for reversion to the poor of land thus freed. He was assassinated. Ten

years later his task was vainly resumed by Caius. The Thorian law of the year 111 B.C. legalized the seizure of the *ager* by the aristocracy and suppressed the payment of all rents for the land. Small holdings were indeed dead. Attempts to reestablish them in Italy and elsewhere resulted in failure, for owners of small parcels of land, since they were unable to compete with the latifundia, hastened to sell their holdings.

The latifundia increased in size under the empire. Coloni succeeded slaves because the large landholder found the colonus less burdensome. Slaves were expensive to buy and expensive to feed, while the colonus, the ancestor of the feudal serf, not only was bound to the soil but also paid dues. The institution of the colonate, which was already in use among the barbarians, was praised by Tacitus and Columella. The emperors encouraged the great landowners to grant personal liberty to their slaves in exchange for payment of a fixed or variable sum, while the small landowners who reappeared or survived looked to the powerful owners for protection. Barbarians who settled on the frontiers in the time of Vespasian and Marcus Aurelius received lands which they worked as coloni. Thus the institution developed.

But the new regime only temporarily revived agricultural prosperity. About 250 A.D. Italy was seized by a tremendous agricultural depression; taxation crushed the farmers and uncertainty darkened their lives; peasant insurrections broke out. Other disturbances occurred when the scarcity of supplies caused an unprecedented rise in prices, and the land was deserted because the tiller of the soil received prices insufficient to cover his costs. The empire was ripe for destruction.

III. GREAT BRITAIN. In the Middle Ages village life was very much the same over most of western Europe. "Everywhere," says Sir William Ashley, "half or more of the tilled land was in the hands of small peasant cultivators. The terms on which most of them occupied their holdings were indeed onerous, and we must take care not to depict their condition in colors too rosy. Yet there they were alike in Central and Northern France, in Southern and Middle England, in Western and Cen-

tral Germany." For our purposes the important features of mediaeval society were the obligation of poor peasants to give bodily labor to their lords, and the fact that in addition to the land cultivated by the peasants there was common waste used by both lord and peasant for pasture. The history of the peoples of western Europe since the Middle Ages is largely the history of the transformation of this common type of society into the different societies that we know today.

The revolts of the agrarian poor in English history are all connected with this transformation. They fall into three classes. The first revolts are revolts against the oppression of the lowest class of cultivator, the villein, by the great lord. The process of commuting bodily services for a money payment began much earlier in England than on the continent. The Black Death in 1348 created a great social disturbance by reducing the population, and since laborers were then scarce, the emancipated peasant demanded higher wages for his labor, and the villein still in bondage grudged services that were now in greater demand than ever. The landlords met this pressure by the Statutes of Labourers, fixing wages, and by trying to check further emancipation. The Peasant Revolt led by John Ball and Wat Tyler in 1381 was the result.

The second kind of revolt is the revolt against the attempt of the lord to enclose the common waste. The disorder of the sixteenth century, illustrated by the rebellion led by Robert Ket in Norfolk in 1549 was provoked by the conduct of the nobles, who enriched themselves by the plunder of the monasteries, and whose avarice had been further excited by the opportunity of making great wealth out of the expanding trade in wool. A gradual process of enclosure of fields by small owners was also going on, particularly in the south of England; and throughout the sixteenth century enclosure and depopulation were subjects of frequent political debate. Enclosure was fiercely denounced by Latimer and criticized by More and Bacon. Parliament put only a slight check on the process. In the eighteenth century there was a further powerful enclosure movement under the influence of the demand for scientific agriculture. As the landlord class was supreme it is not surprising that the smaller peasants, the cottagers and laborers, came off badly in this revolution. It was the fashionable belief of the time that a landless laborer was the best laborer.

Little care therefore was taken of his interests. Cottagers and small farmers who had maintained themselves by their common rights sank into the position of wage earners, without property of any kind. The transformation of the old manorial system was complete and English agrarian society consisted of landlords, tenant farmers and laborers.

The agrarian movements of the nineteenth century were revolts of laborers against low wages and bad social conditions. The Napoleonic wars brought high prices and great suffering. The ruling class, finding that the laborers could not live on their wages, rather than fix a minimum wage, adopted a plan by which laborers' wages were augmented from the public funds in proportion to the number of their children (*see* ALLOWANCE SYSTEM). From this plan there developed various schemes for public employment; the overseers of the poor used to hire out laborers, and in some places laborers were put up for auction. This plan, benevolent in intention, led to the creation of something like a serf class in southern England. Distress and humiliation produced in the southern counties in the winter of 1830 a rising which was suppressed without difficulty and punished with sensational severity—some five hundred men being transported to Australia.

Unions were formed among the agricultural laborers in the eighteen-thirties when the Owenite movement was spreading, but their spirit was crushed in 1834 when six Dorsetshire laborers were transported for taking illegal oaths in accordance with an old fashioned ritual. In the same year the old Poor Law was reformed, and the able bodied laborer was offered the workhouse if he needed help from public funds. The result was a slight rise in wages and the increasing employment of women and children. For forty years the laborer accepted his position. Not only did the conditions of his life and work make combination very difficult, but in the village he had against him farmer, parson and landlord. In the early seventies, however, Joseph Arch succeeded in creating and sustaining for some time a strong agricultural laborers' union. At one time it had almost 100,000 members, and under its pressure wages were raised and conditions improved. But the farmers, supported by the clergy and landlords, with a few distinguished exceptions, organized to destroy the union, and succeeded in weakening it by means of a lock-out. Then came the great agricultural depression; arable

farming declined in favor of pasture, and less labor was needed; by 1881 the union had sunk to 15,000 members, and it was chiefly occupied in helping laborers to emigrate.

The extension of household franchise to the counties in 1884 was followed by legislation, favorable to the laborers, on parish councils, allotments and other questions; and a few years before the war a new spirit of hope was excited by a great Liberal campaign. When the war broke out new unions had been formed and demands were being pressed for a minimum wage and a weekly half holiday. After the war the laborers gained a great advantage in the establishment of an Agricultural Wages Board with wage committees in different counties. Unionism rapidly increased. In 1921 the government repealed the Corn Production Act with its guaranteed prices to the farmer and abolished the Wages Board. But in 1924 the Labor government set up another Wages Board on which representatives of laborers meet the employers' representatives on the district committees as equals. Thus, although wages are still very low, the laborer has acquired a status that he previously lacked.

Irish history presents a complete contrast to English history. In Ireland the agrarian movements have always been peasant movements, for the Irish peasant kept his hold on the soil. The framework within which the struggle went on was the English land system planted on Irish soil. But in the English system the landlord supplied capital and guidance; in Ireland he supplied neither. He was a rent receiver, usually making his home and career in England. (Maria Edgeworth's novel *The Absentee* was written to touch the conscience of these Irish landlords in London.) The Irish peasant consequently looked elsewhere for leadership, and Daniel O'Connell made him a political power. A series of agrarian movements beginning with O'Connell's campaign, and taking different forms under different leaders, compelled the British government to reform the system, banishing, as it was said at the time, political economy to Saturn. The history of land reform in the nineteenth century is the history of the modification of that system in the peasant's favor by Gladstone's successive land acts, which set up fair rent courts and recognized tenant rights. This was but a stage in a revolution, for it was followed by the use of state aid to enable the peasants to buy their farms.

Scottish history has something in common

with English and something in common with Irish history. In the lowlands the agrarian system resembled the English; in the highlands, the Irish. There the typical holding was the crofter holding, and the crofters were as much attached to their land as the Irish peasants. But they were swept away in great numbers by two invasions: the invasion of the sheep breeder and the invasion of rich men who wanted to make great deer forests for sport. The first was denounced by Sir Walter Scott in a famous passage about the unrelenting avarice which was draining the highlands. The evicted crofters emigrated or settled in Glasgow and the towns of the Clyde, where they fostered passionate memories of their wrongs. The process was practically unchecked until the eighties when Gladstone set up a Crofter Commission. The wrongs of the crofters began then to excite widespread sympathy, and Gladstone's government passed an act in 1886 giving security of tenure and fair rents to the crofters in seven counties. Just before the war the Liberal government, after a severe struggle with the Lords, extended the principle of this act to all Scotland.

IV. WESTERN EUROPE. *France*. Throughout western Europe the manorial system, with its hierarchy of ownerships and system of common cultivation, was firmly established by the tenth or eleventh century. But by the fourteenth century peasant tenure in most parts of France, even within the manorial system, had become virtually an independent ownership, encumbered only by manorial rights and royal taxes. During the early period peasant revolts were infrequent, occurring only when situations were particularly unbearable, as at the time of the rigorously suppressed *Jacquerie* of 1358. Beginning in the twelfth and thirteenth centuries, however, there developed in most parts of the country a powerful movement for the emancipation of the serfs. The unrest caused by this movement combined with particular cases of oppression by the noble classes to produce a series of peasant revolts in the succeeding centuries. Of considerable seriousness were the movement of the *Tuchins* in the South (1380-83), the revolts of the *Croquants* during the devastations of the religious wars at the end of the sixteenth century, and the revolt of the

Nu-Picds of Normandy in 1639 after an excessive levy of taxes. Even the reign of Louis XIV was marked by troubles, principally in Lower Brittany, where the revolt of the *Bonnets Rouges* (1675) took on the aspect of a real peasant uprising against the domination of the nobles. But from the beginning of the eighteenth century until the outbreak of the revolution no peasant movements disturbed the peace of the country, although the burdens of the feudal regime do not seem to have been diminished, but were, if anything, increased, especially after 1750.

That dissatisfaction and strong antagonism existed beneath the surface, however, became apparent on the outbreak of the revolution. Throughout these later centuries seigniorial authority was exercised directly not by the lord himself, even when he lived on his estate, but by his officers in charge of the administration of the domain. The residence of the noble on his estate rather than in the city had little effect on the attitude of the peasants; and the belief that in the Vendée or in Brittany relations were more cordial than elsewhere is without adequate historical foundation. For in all parts of France, at the time of the summoning of the Estates-General, those peasants who could make themselves heard in the local *cahiers* demanded the mitigation of the manorial regime, protested against its abuses and asked for the redemption of the most burdensome dues.

This attempt at governmental reform was early complicated by the release of agrarian discontent. One of the consequences of the fall of the Bastille was the *Grande Peur*, a widespread and unorganized peasant movement which resulted in the burning of chateaux and of records and in considerable terrorism. As a result the National Assembly passed the decrees of August, 1789, and of March, 1790, which abolished without indemnity the right of mortmain, hunting and fishing privileges, *banalités* and tolls, and made redeemable the other manorial dues, though on conditions that were onerous for the peasants. Hence serious disturbances again broke out. But after the events of the tenth of August, 1792, agrarian legislation became increasingly democratic in character; until finally, on the seventeenth of July, 1793, the Convention abolished without indemnification all feudal dues. This was the complete and definitive legal abolition of the manorial regime. The subsequent sale of the national domain, first the land of the clergy,

then that of the emigrés, contributed considerably to the increase of peasant ownership. Although it was of particular benefit to the more prosperous peasantry, it also enabled the hitherto landless groups to acquire some property.

Throughout the nineteenth century the characteristic small peasant holdings persisted in France side by side with large and middle sized holdings, to such an extent that on the eve of the World War only 36 percent of the soil was cultivated by large farmers and metayers. Agriculture, still rather primitive up to 1840, developed rapidly in the second half of the century, largely as a result of progress in the means of communication. A serious agricultural depression which began in 1875 and lasted until 1896 led to a series of protective tariff measures which resulted in a rise in prices especially advantageous to the large landholders. But agrarian policy throughout the century was dominated not by the pressure of agrarian movements, for there were none, but by considerations of national welfare.

Because of the low birth rate and of the rural exodus, the number of agricultural workers in France has been relatively small and has decreased still further since the World War. Moreover, although most of the peasant proprietors employ little outside labor, the wages of day workers and of domestic servants have shown marked increases in recent years. Quite recently, too, the accident compensation law was extended to agriculture. It is therefore not surprising that among agricultural laborers the trade union movement has been very weak.

Other types of agrarian organizations have, however, had an important development in France. Agrarian syndicalism, a movement in reality more cooperative than unionist, has grown rapidly since 1890. The *syndicats agricoles* are associations of producers (landholders and farmers of all kinds) one of the chief activities of which is the purchase of fertilizer, machines and tools. The wine producers, especially those in the south, have organized powerful cooperatives not only for the purchase of supplies but also for the sale of their products. More recent is the important movement for the organization of agricultural credit unions to help the peasants in financing the purchase of livestock and even of land. This movement has been supported by the government. A law of August 5, 1920, created a National Office of Agricultural Credit which advances funds to *syndicats*, cooperatives and regional banks

(*caisses régionales*). These institutions may be expected not only to help maintain but also to extend the system of small peasant holdings, which remains one of the most characteristic features of French economic and social life.

Germany and Austria. Although serfdom lasted longer in Germany than in England and France, during the Middle Ages the evolution of the rural classes particularly in western and southern Germany was quite similar to that in France. At the end of the fifteenth and the beginning of the sixteenth century, however, the nobles, and even more the ecclesiastical lords, were making attempts to reenforce their rights, to extend their manorial administration and to encroach upon the communal property of their subjects. This activity was the cause of more and more frequent troubles in southern Germany, as well as in neighboring parts of Switzerland. Numerous understandings of a general character were formed among the peasants (as in the famous *Bundschuh*), and all the movements came to a head in the bloody Peasants' War of 1525. This uprising was in a certain measure reenforced by the Reformation movement, although it is evident from the famous Twelve Articles that the demands of the peasants were essentially of an economic and social character. Luther himself severely criticized the Peasants' War. After a terrible struggle the lords were victorious and the peasants fell back into their former condition of serfdom.

In eastern Germany—Germany beyond the Elbe—the condition of the peasants grew steadily worse after the beginning of the sixteenth century. They were reduced more and more to a position of virtual slavery. The characteristic feature of this evolution was the gradual transformation of the feudal tenure (*Grundherrschaft*) of the lords into estate ownership (*Gutsherrschaft*). The lords, attracted by the gradually increasing price paid for grain exported through the Baltic, undertook the direct exploitation of their estates. This they accomplished through the extinction of a great number of peasant tenures and through forcing the children of their tenants to serve on their lands (*Gesinde*), while prohibiting the emigration of the peasants. The latter were therefore reduced to a condition of subjection closely re-

sembling slavery. This subjection, to be sure, varied in severity in different sections of the country. In Prussia, where the kings were very powerful, the central government succeeded in restricting to a large extent the absolute authority of the lords. But in the eastern part of the Austrian monarchy—Silesia, Bohemia, Moravia—more severe conditions were to be found. The wars of the modern period, and especially the ravages of the Thirty Years' War, greatly aggravated the subjection of the peasants.

The abolition of the feudal regime occurred in western and southern Germany under the influence of the French Revolution. In the Rhine countries annexed to the French state until 1815, this abolition was rapid and radical; elsewhere it was more or less complete and rapid according to the degree of domination that France exercised. In the kingdoms of Württemberg and Bavaria and in Baden peasant emancipation was achieved only in the first half of the nineteenth century. In Austria, as early as the eighteenth century, Maria Theresa and especially Joseph II had, through a series of measures, succeeded in liberating the peasants from their most severe burdens. But after the death of Joseph in 1791 feudal rights were again enforced, and the peasants were not actually freed from the rule of the nobles until after the Revolution of 1848.

In Prussia the abolition of serfdom was the work of the royal government, particularly as directed by the ministers Stein and Hardenberg. Contrary to popular opinion, their reforms were not carried out under the influence of the French Revolution. By the edicts of 1807 and 1809 Stein abolished all servile dues (*Abzugsgeld*, *Gesindegeld*) and suppressed all legal distinctions between the different kinds of property. These arrangements were completed by the *Regulierungsgesetz* of the 14th of September, 1811, promulgated by Hardenberg. According to this legislation the tenant became owner of his holding, but on the condition that he abandon a third or a half of it. The result was an extension of the land owned by nobles, as well as an increase in the number of landless day laborers. Although from 1815 to 1820 there was a marked aristocratic reaction, during the period from 1821 to 1848 legislation favorable to emancipation developed in Silesia and in the province of Posen. A new stage of emancipation was inaugurated by the Revolution of 1848; the laws of the 2nd of March, 1850, abolished without compensation all the

manorial rights and services that still remained.

In eastern Germany, throughout the nineteenth century, an independent landowning peasantry scarcely existed. The land was owned almost entirely by the great nobles (Junkers) who cultivated their own estates through the employment of household servants and day laborers. The condition of the latter was deplorable throughout the whole of the first part of the nineteenth century; in the second half and until 1914 their position improved noticeably, thanks to increasing production, to the rural exodus and to emigration. The wages of household servants also increased, although their living conditions remained very bad. During this time the money wages of day laborers rose on the average 200 percent, real wages 120 percent. There was, however, no diminution in the exodus from the country to the cities, for wage increases were greater in industry. The landowners came to rely more and more upon the seasonal labor of foreigners, particularly Poles.

Unions had been organized among these agricultural laborers and the Social Democratic party had tried to arouse them, but both movements remained ineffective. It is to the Revolution of 1918 and to the German Republic that the German agricultural laborer owes his new and better condition. The republic early abolished all the political and civil restrictions from which he had suffered. As a result of its encouragement to union organization the *Reichslandarbeiterbund* had in 1920 a membership of 65,000; because of its activity the agricultural laborers secured for the first time in German history collective labor agreements, from which two millions of them profited. The state also forced the employers to provide more humane living conditions for farm servants. Its extension of arbitration to include agricultural labor was a reform of especial benefit to families tied to the large estates. For unattached workers the length of the working day was fixed by law—from eight to eleven hours according to the seasons—and through collective agreements wage rates were made uniform. As a result wages were considerably higher than before the war; their further rise was checked by inflation and by the falling off in agricultural output, both consequences of the war.

Italy. The agrarian development of Italy, affected to some extent by the survivals of ancient Roman institutions and more definitely by peculiar geographic conditions and the general historical evolution of the country, was quite different from that of France or Germany. Moreover it did not occur uniformly throughout the country.

In the north the struggle of the prospering cities with the feudal nobles culminated, toward the end of the twelfth century, in the defeat of the nobles. They were made to spend a major part of the year within city walls, and their estates were put under the supervision of that branch of municipal administration which was concerned with the supply of food and raw materials. Under these conditions the servile status of the cultivators could not persist and by the fourteenth century no trace of it was left. At the same time the city bourgeoisie, enriched by commercial and banking activities, was buying up and consolidating nobles' estates. There emerged a system of large estates owned by the city patriciate, managed by employed superintendents along definitely commercial lines and worked by free laborers for wages paid in kind.

In Latium and the neighboring provinces the church acquired much land. Although it farmed this land directly at first, eventually the clerical farm managers, the *rectores* and *defensores*, came to be merely rent collectors from the dependent coloni. Large tenants of church land, the *conductores*, also began to function as collectors of rent, supervisors and even personal lords exacting a labor tribute from the coloni in the adjoining holdings. Although the church was careful not to extend the duration of tenancy beyond thirty years, which would automatically have made the tenancy hereditary, a class of hereditary semi-noble tenants soon appeared on church lands and finally gained almost complete independence of the church.

In the south and in Sicily large landholders used their power to form enormous latifundia at the expense of the state and of the peasant. Their further encroachments were the appropriation of the right of first purchaser of the peasant's produce and the gradual abolition of hereditary tenancies. An increasing area of land was laid under pasture; the position of the peasant, whose customary rights were ignored, became extremely bad. Between him and the landowner there was the large tenant, who

rented the entire estate and received with it the seignorial rights over the peasants. This system of feudalism corrupted by commercialism persisted until the eighteenth century, and in Sicily until the time of Joseph Bonaparte.

Unified Italy inherited a variety of agrarian regimes. The north was dominated by large estates worked by gangs of hired labor marshaled by a contractor. The wages, paid partly in kind, were very low; employment was of a seasonal character and the oppression by the gang captain extreme. Further south prevailed a great variety of metayage arrangements, with the landowner always getting a larger and better half of the crop. This was in fact a disguised form of wage labor, because the landowner directed through his manager a great many of the agricultural processes of his tenants. The poverty of the agriculturists was reflected in a diet based on maize, which caused frequent epidemics of pellagra. Still further south and in Sicily the latifundium remained the usual type of agricultural enterprise in the plains and valleys, while small peasant farms were prevalent in the mountainous districts. The latifundium was usually rented in its entirety to an entrepreneur, who exploited a part of it himself and subleased the rest, which in its turn would frequently pass through the same process of leasing and subleasing.

On the whole the situation was characterized by absentee ownership and the prevalence of large estates. The old agrarian systems were imposed upon a commercialized agriculture. The resulting dependence of the lower classes, with their slender income, upon market fluctuations of the prices of agricultural produce made their condition worse than it had ever been before.

The government of the new state was at first interested only in the complete abolition of feudal restrictions on the circulation of land. Even when the official investigation in the early eighties revealed the unusual squalor of life of the rural masses, little else was done than the passing of unenforceable laws providing for the reclamation of marshy lands, the breeding places of malaria. The agricultural laborer and tenant were therefore in a state of continuous unrest and willingly joined labor unions even when the latter were illegal (1885-1900). This inclination to combined action was strengthened by the fact that in many districts the entire rural population lived in large villages.

In 1891 the abolition of *usi civici* led to

clashes in the rural territory surrounding Rome. In the same year the *fasci* were organized in southern Italy; brought into life by radical agitation, these unions were a characteristic manifestation of peasant psychology with its faith that Christ and the king would support their demands for improved conditions. In 1893 a serious revolt led by peasant leagues broke out in Sicily. It was repeated on a smaller scale a decade later. After 1900 the agricultural labor unions were tolerated and in some cases encouraged by the government. The entire north was soon covered by a net of such unions federated provincially. Later an interprovincial Federazione Nazionale dei Lavoratori della Terra came into being. The most important achievement of these unions was the securing of collective contracts by which the unions supplanted the commercial gang leaders and with the aid of which they were able to obtain higher wages and a more equitable distribution of employment. Within a decade the small metayers found their interests antagonistic to those of labor and seceded from the labor unions to form autonomous leagues which were later often active in concert with the landowners. At the same time the landowners perfected provincial and interprovincial organizations of their own, so that by 1910 the successes of the agricultural labor unions were checked. Attention was then turned to collective leaseholds which were either collectively worked and managed enterprises or combinations of small tenancies for certain limited purposes. While the militant unions were led by socialists and syndicalists, the Catholics were fostering the development of agricultural cooperation, a movement which grew rapidly and whose several branches were brought together in the national Federazione Italiana dei Consorzi Agrari.

Troubles broke out again in the years following the World War, when the slogan "La terra ai contadini" (land for the peasants) was heard throughout Italy. The legislation of the war and post-war years, which provided for the temporary seizure of uncultivated or not properly cultivated lands and of lands which were not improved in accordance with preceding laws, could not stem the tide of forcible occupation of land by the peasants, which continued until the establishment of the Fascist regime.

On the whole little has been achieved either by mass pressure or by governmental measures. The most promising step of the government, an attempt to reclaim land and establish small

holdings, failed because of lack of funds in the treasury and dearth of private capital. The position of the Italian agriculturist is still greatly in need of improvement.

HENRI SÉE

Denmark. Agriculture in Denmark is more than a method of farming; it is a political system and a culture. In Denmark the state is rural rather than urban, agricultural rather than commercial. It is ruled by the farmers in their own interest and its educational, cultural and political agencies are dedicated to concern for their welfare and to the most advantageous distribution of their products.

About 1870 the competition of American wheat fields and the protective tariff policy of Germany had reduced Denmark to industrial straits. The people were sinking into despair, and the peasants seemed doomed to bankruptcy. But the very difficulty of the situation stimulated the peasants to efforts which within the next fifty years made Denmark a peasant democracy. Most observers have traced the origin of this change to the activities of Bishop Grundtvig, who gave his life to the development of an educational system that was democratic and suited to an agricultural population. The work of Grundtvig was associated with the development of the people's high schools, which as far as the farmers are concerned are the central feature of the educational system of the country. These schools are not vocational, but fuse culture with vocational education and aim to educate all the people. Not maintained by the state, they are completely self-governing and in a large measure self-supporting through their fees and some local aid. The principal of one of these high schools is almost always a man of distinction, who is responsible to no one but his community for the innovations he may introduce or the methods he may use. The schools are for adults between sixteen and forty years of age, and every peasant hopes to spend at least one term at one of them. These schools have contributed both to the development of cooperation and to the democratization of the Danish state.

The cooperative society is the second agency of agricultural organization in Denmark. Of the 200,000 farmers of Denmark, 184,000 are members of the more than 5000 different co-

operative societies in the country. These societies deal with almost every known necessity, but the dairy cooperatives are by far the most numerous. All the societies are aided by the state in a variety of ways. They have developed a high degree of business skill, and compact and loyal organizations. Almost every farmer is a member of several such societies. Through them he prepares for market his own butter and cheese, bacon and eggs, and exports them to London. In addition he is a member of a distributive society through which practically everything he consumes is purchased. Indeed the entire agricultural life of Denmark is centered around the cooperative society.

The Danish state is a farmers' state. The peasants have a large representation in the Parliament and control the ministry, of which many members are farmers. In recent years the very small peasants known as *husmaend*, owning possibly a half acre of land, have been rising to power in cooperation with the socialists. In this sense Denmark is a class state. The peasants have used their power to nationalize the railways, which are made to serve their export business. They have adjusted taxation to their interest and in recent years the movement for the single tax on land values has made substantial progress, more progress than in any other country in the world. The farmers have, however, been very generous in their social legislation and their provisions for social insurance, while trade unions are very strong and are encouraged by the state.

As a result of this class control, the few remaining feudal estates have been largely expropriated and divided into small holdings. The state has created credit funds to be loaned to prospective farmers who can convince local committees of their ability. For such persons the state provides ready made and fully equipped farms from the land taken from the large estates. In line with this policy tenancy has been very greatly reduced.

Denmark is a state that is consciously planned. It is an exhibit of agricultural efficiency. In no country in Europe are education and culture so widely diffused, in no country is landlordism so nearly extinguished, and in no state in Europe has economic democracy evolved with so much intelligence as in Denmark.

FREDERIC C. HOWE

See: FOLK SCHOOLS; DAIRY INDUSTRY; AGRICULTURAL COOPERATION.

V. EASTERN EUROPE. *East Central Europe and the Balkan Countries.* By the beginning of the eighteenth century serfdom was well established in most parts of southeastern Europe. In the Alpine lands the peasant still enjoyed a considerable measure of freedom, but elsewhere he was bound to the soil; and in countries like Bohemia, Moravia, Lower Austria, Galicia and parts of Hungary, where the lords cultivated on a large scale themselves (system of *Gutsherrschaft*), he owed important labor services (*Robot*) to his lord. In the Czech countries the old native aristocracy had been overthrown at the battle of the White Mountain (1620), and the serfs were subject to alien control.

It was not until the advent of Maria Theresa in 1740 that the centralized Hapsburg monarchy was strong enough to check the growing power of the feudal lords. As taxation fell almost exclusively on peasant land, encroachment by the lords meant a loss of revenue to the crown and was declared illegal in 1751. The treasury had also an obvious interest in checking the constant increase in the dues and services owed by the peasantry to their lords. Maria Theresa therefore regulated and codified the existing obligations in the kingdom of Hungary by the *Urbarium* of 1767, and applied the same general principle to Bohemia and Moravia eight years later. On the crown domains she went still further, abolishing the servile status and introducing money rentals in place of dues and services. Her son Joseph II attempted to extend this policy to all domains. In 1781 he abolished the servile status in the Bohemian lands in a document known as *Leib-eigenschaftsaufhebungspatent* and issued a series of decrees between 1785 and 1789 reducing the obligations of the peasantry to their lords and transforming them into money payments. Unfortunately these last measures broke down in practice and were withdrawn by the disillusioned monarch a month before his death in 1790. Reform from above had failed, and reaction was to persist for over half a century.

But the example of the French Revolution and the slow growth of a new national feeling were not without effect. Count Szechenyi succeeded in obtaining freedom of migration for the Hungarian peasant in 1836, while a fierce peasant revolt in Galicia ten years later forced the agrarian problem upon the attention of an apathetic central government in Vienna. By 1848 the Danubian peasant had become class conscious, and a number of bad harvests in-

furiated him still more against the feudal privileges enjoyed by his lord. The revolution shook the old political regime, and on July 26, 1848, the new Constituent Reichstag at Vienna, in which nearly a quarter of the deputies were peasants, declared that "from now on, servile status, with all rights and duties springing therefrom, is abolished." A patent issued on September 7th gave effect to this resolution. The distinction between noble and peasant land disappeared, the peasantry acquiring the latter in full individual ownership. All obligations arising from personal subjection were abolished without compensation, while the money value of the dues and services was to be assessed by a government commission and was in fact ultimately paid off with government assistance. These principles were applied to Hungary, with some modifications, after the suppression of the great national rebellion of 1849.

In the basin of the lower Danube national and agrarian emancipation went hand in hand. A Serbian law of 1839 gave the peasants full proprietary rights over the land actually held by them six years previously, and the former Turkish lords lost their influence. In the Rumanian principalities the revolt led by Tudor Vladimirescu in 1821 was an outward sign of agrarian discontent, but when the Russians occupied the country and issued a constitution (the *Règlement organique* of 1831) they merely codified existing agrarian relationships. It was left to Prince Cuza, the first ruler of the united country, to strike at the root of feudal privilege. In 1863 he secularized the church lands, but his proposal to emancipate the serfs and abolish labor services (*claca*) met with such intense opposition from the aristocracy that he disregarded the constitution and issued the comprehensive Rural Law on his own initiative in 1864. The former serfs obtained, in full ownership, a quota of land varying according to the number of oxen they possessed, while compensation to the lords in respect of labor services and tithe, which were now abolished, was paid for the most part by the state.

In Bosnia and Macedonia agrarian feudalism still survived under Turkish (and Austrian) rule, but elsewhere in the Danubian region the peasantry had by the sixties been emancipated from serfdom. Under the individualistic legislation of the period, the clan settlement (*zadruga*), which prevailed among the upland pastoralists in the southern Slav lands, rapidly disappeared. Here, as elsewhere, the peasants

lost the protection of custom before they were able to use contractual freedom. They were, indeed, singularly ill-prepared to face the rapid economic changes of the new era. With the advent of railways, a money economy and international trade, the days of the self-sufficing village community were numbered, and the rapid increase in population soon created a veritable land hunger.

The legislation of 1848 and 1864 had left what was once "noble" land in the hands of its former owners, and very large estates still played an important role in the rural economy of the Danubian lands. In Bohemia properties of over 125 acres comprised 41 percent of the total area, and some of these were of truly princely dimensions. The same was true of Hungary, where estates of over 140 acres occupied nearly 56 percent of the total area, while in the Old Kingdom of Rumania 48.5 percent of the arable land was in the hands of owners of 250 acres or over. The agrarian structure of these countries was thus dangerously top-heavy. Many of the landlords were absentees, and their land was often leased out on a produce-sharing tenancy (*metayage*). In parts of southern and eastern Hungary labor services were established on a contractual basis, and bad harvests led to considerable unrest in the nineties. Throughout the Dual Monarchy the regions of latifundia were those which sent their dissatisfied but enterprising peasant sons to seek a new home across the ocean. In Rumania the exactions of lessee trusts led to the last of a series of peasant revolts in 1907, and the agrarian question dominated the political stage in 1914. In many areas, such as Bohemia, Slovakia, Transylvania and parts of southern Hungary, the landed aristocracy was alien in race and sympathies to the majority of the population, and the land problem was national as well as social.

Then came the World War, with its profound effects on the psychology of the masses as well as on their material well being; the break-up of Russia, with its example of a new agrarian practise; and finally the collapse of the Central Powers and the formation of new national states. The old agrarian order was doomed.

While the German armies were overrunning the country, a Rumanian Constituent Assembly, composed mainly of landlords, voted the principle of the expropriation of the large estates in June, 1917, and, on the battlefield of

Mărășești a few weeks later, King Ferdinand gave a solemn promise that the crown domains should be divided among the peasants. On December 15, 1918, the government issued a decree which filled in the details of agrarian reform. Land belonging to absentees and corporations was expropriated in its entirety, while other owners were called upon to surrender some five million acres of arable land according to a sliding scale which left owners of 250 acres or less untouched, but allowed no proprietor to keep more than 1250 acres. The provisional government of Bessarabia had already passed a revolutionary law expropriating all land over and above an allowed minimum of 250 acres, and the national assemblies of Transylvania and Bukowina made agrarian reform a condition of their union with the Old Kingdom. Finally acts passed in July, 1921, codified the earlier decrees and established a new scale of expropriation which was more severe but also more scientific. Compensation, which was given in government bonds from 1918 onwards, has become negligible as a result of the depreciation in the national currency.

In Czechoslovakia agrarian reform was almost equally drastic, but it has been applied more slowly. A law of April 16, 1919, placed all estates of over 375 acres of arable, or 625 acres of all land, under sequestration; they could not be disposed of without the consent of a specially constituted government land office. The law of May 27, 1919, gave small holders proprietary rights over such land as they had rented from the large estates since 1901; moreover, from 1920 onwards, sequestered land has been divided up among landless peasants and others. The expropriated "home farms" (*Restgüter*), however, have been maintained intact. The division of the arable land will be completed by the end of 1929, when the former landlords will have lost a total of over 3,000,000 acres of arable land and nearly 7,000,000 acres of other land. Compensation is paid on the basis of land prices in the period 1913-15, and no allowance is made for currency depreciation since that time.

Agrarian reform in Yugoslavia has been somewhat chaotic. A decree of February 25, 1919, contained certain "preliminary instructions" providing *inter alia* for the abolition of the servile status, which still survived in Bosnia and Macedonia; the suppression of the colonate, a semi-servile form of metayage tenure common in Dalmatia; the expropriation of the large estates, especially in Croatia and what was once

southern Hungary; and the nationalization of the forests. This was supplemented later by a number of confused and often contradictory decrees, and approximately 3,000,000 acres of land (less than half of which is arable) have been taken from the large estates. Schemes of internal colonization have not usually proved successful, and the reform has been carried out on political rather than scientific lines.

In Austria large estates accounted for only 6 percent of the total arable land, and agrarian reform was virtually limited to the Resettlement Law of May, 1919, which restored to the small cultivator former peasant land acquired for sporting purposes since 1870. The case of Hungary, however, is in marked contrast to that of its neighbors. The revolutionary agrarian legislation passed by Bela Kun in 1919 did not survive the Bolshevik regime. A law passed by his successors in December, 1920, did little more than give the government a first refusal of all rural property offered for sale, while recognizing the rights of certain categories of persons (especially the so-called "heroes") to allotments. Some of the land acquired under the capital levy scheme has also been used for settlement, but properties of 140 acres and over still compose nearly half of the total area of the country. Hungary is an island of latifundia in a green sea of agrarian reform.

Elsewhere the day of the feudal hierarchy is virtually over. The peasant is slowly becoming an important factor in politics and his standard of living has undoubtedly risen. But the change in land ownership has not been accompanied by a corresponding change in the average unit of production. Approximately one half of the large estates in Old Rumania, for example, were formerly leased out to small cultivators, and it is estimated that not more than 7 percent of the total arable land in Czechoslovakia has passed from large to small scale production in consequence of the reform. Moreover peasant holdings of inadequate size have been augmented. The growth of rural education and agricultural cooperation should, however, lead to increased efficiency in the future. The social results of this recent legislation are most far reaching; agrarian reform has opened out new possibilities in the lives of the masses of the people.

European Russia. As early as the fourteenth century the position of free agricultural tenants in Russia was somewhat similar to that of personal serfs. In 1597 Boris Godunov completed the series of enactments and legalized the customary rules which bound the cultivator to the soil. During the next two centuries serfdom spread over an increasing territory, and the position of the serf became almost indistinguishable from that of a slave; by the end of the eighteenth century he could even be sold apart from the land to which he was presumably attached.

Serfdom had many economic and political functions. It was first of all a primary source of agricultural labor, and in the primitive condition of Russian agriculture labor was the most important factor in production. The value of a piece of landed property was determined largely by the number of serfs bound to it. From the point of view of the government also, serfdom was essential, for its assurance of continuity of forced labor (*barshchina*) or of money dues (*obrok*) furnished in the early years a stable economic basis for the military and administrative officialdom. Later serfdom performed the same function in assuring the prosperity of the gentry, who were themselves obliged to serve the state. The repeal of this obligation in 1762 removed one of the most widely accepted justifications of serfdom and led to discussion of its abolition. Pugachev attempted to make use of this sentiment in the revolt which he led a decade later. Serfdom also facilitated the control of the government over an immense and undeveloped territory. The landowner was made responsible for the preservation of peace and order, the collection of taxes, the provision of assistance when crops failed, and recruiting for the army. This devolution of powers is suggestive of the early stages of most colonial governments. The landowners, however, were not in all cases the base of the administrative hierarchy concerned with the rural population. The serfs attached to larger estates, especially to the *obrok* estates of the absentees, developed their own corporate organization, tolerated because it was an agency through which the joint responsibility of all the serfs for various dues and taxes could be enforced. This organization, the very existence of which stimulated class consciousness and self-government, influenced the later development under legal sanction of the land commune (*obshchina* or *mir*) with its pronounced tendencies toward equalization of land distribution.

The abolition of serfdom was accomplished in Russia by a decree of Alexander II in 1861. A number of factors had combined to bring about this change in policy. The spread of western ideas in governmental, social and literary circles; the frequency of local uprisings; a growing realization of the economic advantages of free labor; the necessity of maintaining Russia's prestige which had been shaken by the Crimean War, were all of importance. The act abolishing serfdom has been characterized as "the greatest legislative act in history," but it might also be said to have created the greatest economic maladjustments.

This act, supplemented and amended by later enactments, proclaimed the legal freedom of the former serfs and made provisions for a land settlement. The emancipated serfs were to receive individual grants of cottage and kitchen-garden land and communal grants of arable, pasture and meadow land. The state paid the former landowners in bonds and the peasants were required to repay in instalments. Alienation of allotment land (*nadel*) to non-peasants was restricted by a law of 1893. The small size of most holdings made it impossible for the peasants to make their payments, and the mortgage debt, principal and overdue interest, was canceled by law in 1906. Even with this relief, however, the situation remained unsatisfactory.

In Russia proper the power to regulate the use of the newly acquired communal land was granted to the land commune (*obshchina*), a body composed of the heads of the households of a given manorial area, which adopted decisions by a two-thirds vote. General redistribution of the communal land among its members was allowed at intervals of not less than twelve years by the terms of a law of 1894. The component of this land commune was, and as a working unit still remains, the family, headed by an elder, whose powers were considerable, and carrying joint responsibility for the obligations and arrears of all its members. The right of an adult married member of such a family to claim the carving out of a separate holding was granted only in 1886, and then only on condition that reasonable cause of family dissent be shown, and also that authorization of the *mir* be secured.

The liberated serfs (about 22,000,000) together with the state and crown peasants (about 9,000,000) formed a peasant class with a special legal status. To give effect to this position

they were organized in local corporations (*selskoe obshchestvo*) with elected executives, and possessed of certain administrative and judicial powers. It was through these corporations that the government enforced the joint responsibility of the peasants for arrears in taxes and the performance of statute labor, such as road repairs, and military service. From 1861 until 1913 this class was subject to the jurisdiction of its own elected judges or courts (*volostnoy sud*), which based their decisions largely on customary law. This legal status involved certain disabilities. Only the peasants, for instance, were subject to the sentence of corporal punishment. According to the Zemstvo Statute of 1864 the peasants constituted a separate group in elections to rural local government bodies (*zemstvo*); and later the same provision was made concerning elections to the national legislature (Duma). With the revolution of 1905 some of these disabilities lapsed and the status of the freed serf approximated more nearly that of a full citizen.

After 1861 there had been an unmistakable economic decline in the densely populated agricultural districts of central Russia. Elaborate official and *zemstvo* statistics showed in detail that the majority of the peasants had inadequate holdings, were underfed, underemployed, in arrears with taxes and were paying exorbitant rents for extra-allotment land. While in 1861 only 28 percent had inadequate holdings, in 1914 the proportion was probably about 70 percent.

Four notable and interrelated remedies for this situation were widely debated: more land for the peasants, industrialization of the country, improved methods of cultivation, and birth control. The last was completely out of the question, and the first was the most popular both among peasants with inadequate holdings and among liberal and revolutionary groups. The pressure in this direction monopolized the nation's attention. The purchase by peasants of 100,000,000 acres in the period 1862-1914, chiefly through the Peasants' Bank, and the settlement of millions of peasants in Asiatic Russia accomplished but little compared with the magnitude of the problem. And though by 1914 the peasantry owned four fifths of the arable land in European Russia, their land hunger was far from satiated.

Probably the only practicable solution of these difficulties was to be sought in improved cultivation by the individual, free from communal

control and master of a compact holding. Stolypin aimed at such a change in the ukase of November, 1906, which, with further modifications intended to encourage individual cultivation, was made law by the Duma in 1910. Two types of peasants responded to the new opportunity: those who wanted a full sized manageable holding, and those who wanted to get rid of communal and family restrictions in order to sell their uneconomic holdings and find outside employment. Between 1907 and 1913 no less than one fifth of the farms under communal tenure (or 2,478,000 peasants with holdings of 45,900,000 acres) claimed separation from the commune; 24 percent of the claims were satisfied without the consent of the communes. In addition 3,500,000 in communes where redistribution of land had been in abeyance for twenty-four years became individual owners. The opportunity for individual ownership was welcomed by the many peasants who had been restive under family control and power vested in heads of households. As a result of these changes the village commune and patriarchal family arrangements were being replaced gradually by a system of economic individualism.

Then in the revolution of 1917-18 all non-peasant land and all peasant lands held in private ownership were seized by the land communes on behalf of the majority with inadequate holdings. This was not organized nationalization, but a chaotic performance carried out in piecemeal fashion by several hundred thousands of communes. It indicates clearly the importance of the agrarian aspect of the whole revolution. The resulting average accretion of land per peasant holding was 22.5 percent, or from 5 to 6 acres per head of the farming population, but the increase was smaller in the densely populated regions and everywhere most holdings remain very much below the limit indispensable for bare subsistence under the present mode of cultivation. On January 5, 1918, the Constituent Assembly passed the Fundamental Land Act prepared by the Social-Revolutionary party. It proclaimed that "the right of private property over land within the borders of the Republic is henceforward abolished once and forever." The main features of this act were incorporated in the Soviet Land Code of 1922. The emphasis at first laid on the right of the land commune to distribute the land according to the labor power of those who worked it was, however, lightened under the New Economic Policy. Articles 134-137 of

the code revert to the Stolypin reforms by facilitating separation of the individual cultivator from the land commune. There is this important difference, however, that the family reappears as a collective labor unit and that peasant land cannot be held as unrestricted private property.

Poland and Lithuania. Probably because of the slowness with which the subjection of the peasants occurred, there were almost no peasant uprisings in Poland in the early years of its history. By the seventeenth and eighteenth centuries, when serfdom was breaking down in western Europe, in Poland it was at the height of its development, with land and power concentrated in the hands of the nobility, and king and towns extremely weak. It was in this period that agrarian movements became important.

Although from time to time individual landowners advocated reforms, the majority of the gentry were opposed to change. Their reluctance to take any decisive action, even during the partitions of Poland, gave the foreign conquerors the opportunity to play the part of liberators. The peasants so definitely regarded the invaders as their benefactors that subsequent nationalist movements were condemned to failure. For instance, during the nationalist uprising in Galicia in 1846 the peasants themselves organized a massacre of the Polish landlords and thus crushed the rebellion.

Unrest and demands for land and personal freedom on the part of the peasants increased between 1846 and 1864. The emancipation of the serfs in Prussia (1848) and in Galicia (1849) caused the peasants in the Russian section to clamor more insistently for reforms. Seeing the necessity for some action, the Polish leaders and the Russian government tried to anticipate each other in satisfying these demands. The leaders of the Polish nationalist insurrection of 1863 issued a manifesto proclaiming the emancipation of the serfs. The Russian government countered in 1864 with a similar decree, which effectively quelled the uprising.

But none of these acts of emancipation solved the economic problems of the peasants. Many were left without land, and even those with holdings lacked adequate capital or credit facilities. In Prussian Poland there set in a

strong wave of emigration to the United States and Germany. In Russian Poland the surplus rural population found employment in the newly organized industries. But in Galicia, where there was little emigration, and industrial employment was scarce, the onerous position of the peasants resulted in a populist peasant movement which later developed into the strongest of the Polish peasant parties. This particular movement also began to take on the tinge of nationalism. Although several proposals for general land reforms were made before the World War, nothing of importance was accomplished until the creation of the independent Polish state. Indeed just before the post-war reforms, 31 percent of the agricultural population consisted of landless peasants, while less than 1 percent owned 31 percent of the total land.

The Polish Land Reform Bill, enacted in 1920, was passed under pressure of the necessity for national unity in the face of the threatened Russian invasion. It provided for the creation of a land reserve, consisting of crown land, of confiscated estates of former officials, of certain church properties and of land from private estates in excess of 180 hectares. Compensation for the property seized was fixed at 50 percent of its market value. The land from this reserve was to be parceled out to landless peasants in lots of 15 hectares and in varying proportions to peasants whose holdings were less than 23 hectares in extent. Numerous difficulties have been encountered in the carrying out of these reforms. Perhaps the greatest obstacle to the realization of the desired changes has been the lack of funds in the state treasury.

As long as Lithuania was a part of Poland, the two countries had similar agrarian difficulties. Antagonism between nobles and serfs was heightened in Lithuania, however, by the Polishization of the nobility in the face of continued loyalty of the peasants to Lithuanian customs and language. Russian annexation resulted in still worse conditions for the peasants, and it was not until 1861 that the government decreed the emancipation of the serfs and enforced some distribution of land. Following an insurrection of 1863 the Russian government inaugurated an attempt at compulsory Russification, involving the suppression of the Lithuanian language and the Catholic religion. The opposition aroused by this policy led to frequent confiscation of land by the government.

A national populist movement sponsored in this period by Lithuanian intelligentsia became later the backbone of the struggle for Lithuanian independence.

The gravity of the economic condition of the peasants was striking; just before the war 17 percent of them were landless and 28 percent owned no more than 3 hectares of land. Although here, as in Poland, attempts were made to secure agrarian reforms before the war, it was only after 1918, when Lithuania became independent, that anything was accomplished. The Agrarian Reform Law, passed by the Constituent Assembly of Lithuania in 1922, provided for the expropriation of owners of large estates, with some compensation, and the distribution of the land to landless peasants and to those with very small holdings. As a result of this legislation many new farms have been created, and the situation of the peasantry has materially improved.

Latvia and Esthonia. Agrarian movements in Latvia and Esthonia have been to some extent also nationalist movements. The original free inhabitants of the country had been converted into serfs in the thirteenth century, when the German Knights of the Teutonic Order seized the land on the pretext of converting its peoples to Christianity. The opposition of the peasants to these German lords persisted for many centuries; among the more important of the continual uprisings to which it led were those of 1343, 1560, 1784, 1805, and those during the forties and fifties of the nineteenth century.

Throughout these years the position of the peasantry depended also on the attitude of the frequently changing governments, for Poland, Sweden and Russia in turn controlled the two countries. In 1681 Sweden attempted to abolish serfdom and reform conditions of tenure; but when Russia acquired the countries in 1721 the Swedish laws were abolished, and the landlords went so far in their oppression of the peasants that the Russian government intervened with a measure of protection. Governmental interest was further stimulated by the French Revolution, and there resulted in Latvia in 1804 a reform which gave the peasants hereditary leasehold of the land.

This situation, however, was changed by the

reforms of 1816 in Esthonia and of 1819 in Latvia, which emancipated the serfs without providing grants of land, and thus left the peasantry virtually destitute. Widespread emigration and recurring revolts followed. After 1841 a series of regulations delimiting the area of peasants' land and regulating the rights of leaseholders was passed. While these regulations introduced some improvements in the conditions of the peasants, they did not materially lessen agrarian unrest, for most of the land which the peasant tilled still remained the property of the lord.

Since the national and the agrarian movements in Latvia and Esthonia were both directed against the German aristocracy, it was natural that there should have been an early identification of the two and that national independence brought with it agrarian reform. The radical character of the post-war reform laws in these countries was due to the fact that the landowners constituted a group nationally and culturally alien to the majority of the population of the two newly created states, as well as to the influence of the Russian Revolution and the Soviet invasion. These reform laws expropriated the owners of large estates and parceled out their land among the peasants. In Esthonia former owners were compensated, but in Latvia they received no compensation. The number of small farms in both countries has increased tremendously as a result of this legislation. Whereas in Latvia before the reform the peasants had owned only 39 percent of the total land, by 1923 holdings of from 2 to 50 hectares in extent comprised 81 percent of the land, and in Esthonia the percentage of the total land in small holdings increased from 42 percent in 1919 to 87 percent in 1924. As far as one can judge, the reforms have resulted in notable improvements in the conditions of the peasantry in both countries.

VI. UNITED STATES. During the colonial period of American history agricultural interests dominated the legislatures of the southern colonies almost exclusively. Such agrarianism as there was in that section was directed against the imperial policy of Great Britain, which was formulated in the interest of the British commercial classes. An important contributing

factor in producing revolutionary zeal among southern colonial planters was their feeling that they were victimized by the merchants in Great Britain from whom they purchased their supplies and to whom they sold their crops. Hence it may be said that so far as the South was concerned the American Revolution itself was an agrarian movement. In the North the colonial governments were usually dominated by the mercantile interests of the seaboard towns. In contrast to the South, where agriculture was carried on "as a business," in the North the farmer usually farmed "for a living." He was frequently a debtor to the city merchant or shopkeeper. During and immediately after the revolution his debts tended to increase, this condition becoming particularly intense in Massachusetts and Rhode Island. In both these states the farmers attempted to obtain control of the state governments, pass stay laws against the execution of mortgage foreclosures and provide for the emission of large quantities of paper money with which they might liquidate their indebtedness. They obtained control of the government in Rhode Island, issued paper money in abundance and almost literally thrust it down the throats of their protesting creditors. In Massachusetts, however, the efforts of the farmers met with no such success. In the western part of the state many of them united under the leadership of Daniel Shays, marched boldly into the courts and prevented the transaction of legal business. But troops were called out and Shays' mob was dispersed.

In the period 1783-87 while these disturbances were taking place in Massachusetts and Rhode Island, vested interests in the United States were neither very numerous nor united. Nevertheless they were class conscious and alert against dangers that threatened to curtail their development or seemed likely to jeopardize the position they had already attained. To aid these interests the federal constitution was brought into existence in 1787-89. During the ensuing twelve years while the Federalist party retained control of the central government, the financial, foreign and taxation policies of the United States were designed to assist the commercial, manufacturing, banking and speculative groups. The theory upon which Hamilton and other Federalists based their arguments in favor of such policies was that by advancing the interests of these groups directly, other groups, particularly the agricultural, would benefit indirectly. While at no time since Ham-

ilton's day have those in control of the federal government stated their theories so boldly and frankly, it may well be maintained that in practise, with some minor exceptions, the policy of the government has never changed. At the same time other classes than these which may be designated as "business interests" have more or less unconsciously acquiesced in this theory.

From time to time the farmers, particularly the producers of such great staple agricultural crops as rice, cotton, tobacco, grain and meat, have protested. They have argued that their industry is basic and that consequently their prosperity should be the primary and direct concern of the government. The first American statesman of importance to hold this view was Thomas Jefferson. He succeeded in building up a great political organization composed in the main of western frontier farmers and a majority of the southern planters. The bond of union among his followers was opposition to the privileges that had been bestowed upon the business groups by the Federalists. They had no constructive program of their own comparable to that which the Federalists had put into execution. Hence aside from strict economy in the administration of the government and the purchase of Louisiana, which may be considered an agrarian policy, Jefferson's administration was of a negative character. His effort to curb the power of the Supreme Court failed and very little of the Federalist program was undone.

Under Jefferson's successors, Madison, Monroe and John Quincy Adams, the Republican party became almost as much a party of the business groups as the old Federalist had been. The frontier farmers and the southern planters became restive and with the assistance of certain labor groups in the eastern cities elected their candidate, Andrew Jackson, to the presidency in 1828 against John Quincy Adams. Again the results were on the whole negative. The destruction of the Second Bank of the United States, the lowering of the protective tariff, the removal of more Indians west of the Mississippi, and the appointment to the chief justiceship of a man less amenable to the dictates of the business interests than John Marshall had been, were the principal accomplishments of the Jacksonian epoch from an agrarian standpoint.

From Jackson's time to the Civil War, agriculture in the United States was relatively prosperous, but those engaged in it tended to

divide into three fairly well marked groups: the southern planters, the western grain growers and the eastern truck farmers. The last of these generally identified their interests more or less completely with those of the business people of the cities to whom they sold their produce, and in politics they usually followed the lead of the business men. Although mutually suspicious, the other two agricultural groups tended to act together in politics and exerted sufficient influence in Washington from 1830 to 1860 to hold the balance between agriculture and other forms of business enterprise more nearly even than has been the case since the Civil War. Between 1850 and 1860 the two groups diverged rapidly over the questions of a free land policy, slavery extension, government aid to transportation facilities and a persistent imponderable—the morality of slavery. The new Republican party which came into power in 1860 was an alliance between the eastern business interests with their satellites—the eastern truck farmers—and the western grain growers. The southern planters, rendered desperate by their loss of influence in the national government resulting from this alliance, and unwilling to submit tamely to impotent isolation, carried their states into secession and undertook the task of establishing a separate confederacy of their own. In the Civil War that followed, the southern planters lost all—their Confederate government, control of their state governments, most of their landed property, all their slave property and finally their own peculiar form of agricultural organization.

With the collapse of the most articulate agricultural group that has ever existed in the United States, business interests entered upon a period of almost unchallenged control of the federal government and most of the state governments. Far from being hindered by government regulation, they received at the hands of the central and local governments every favor they desired. The Hamiltonian theory was practised with almost no qualifications. What could not be gained by fair means was frequently obtained unfairly. Despite some talk about "the corrupt alliance between big business and politics," the people of little or no means accepted the situation cheerfully, for in the main, so far as they thought about the matter at all, they believed it best to let business men, whose wisdom had been manifested by their success, control the governments in

their own interests, and hoped that some of the wonderful prosperity might eventually overflow to their own benefit.

Such dissent as there was came mainly from western grain and meat producers. During the Civil War these farmers had been prosperous, but with the cessation of hostilities came a rapid decline in their affluence. Foremost among the factors contributing to this result was deflation of the currency. This, coupled with an increase in the supply of agricultural commodities, due in part to the opening up of new grain lands under the generous provisions of the Homestead Act of 1862, brought a period of low prices, which with few interruptions lasted until the close of the century. There was no decline in interest rates, and the principal of such debts as the farmers had contracted had to be repaid in a dollar of enhanced value. Furthermore the prices of commodities which the farmers had to buy did not decline in a ratio commensurate to those they sold. Consequently many farmers demanded that the government cease its policy of contraction and enter upon one of inflation of the currency until prices were again somewhere near their war-time level. Failing in their efforts to secure endorsement of their demand from the old parties, some of the farmers organized the Greenback party and put candidates in the field for the presidency and for Congress during the years 1876-84. This attempt having failed, they turned their attention to the question of "free silver" (*q.v.*). Silver had been demonetized in 1873, but soon afterwards there was a rapid increase in the amount mined. The agrarians believed that if it could be re-monetized at the old ratio of 16 to 1 with gold there would follow an inflation of sufficient proportions to give them relief. In 1878 they succeeded in having Congress enact a silver-purchase law. This gave some relief, but after a time the farmers again grew dissatisfied and demanded more silver. In 1890 this was granted in a new silver-purchase act. Then followed the panic of 1893, and still harder times for the farmers. President Cleveland, solicitous about the safety of the gold reserve, induced Congress to repeal the silver-purchase act. Even before this the farmers of the West, aided by some from the South, had organized the Populist party and demanded, among other things such as government ownership of railroads, telegraph and telephone lines, the free and unlimited coinage of silver at the 16 to 1 ratio.

Aggrieved at the action of Congress and President Cleveland, the silverites attacked with new vigor and in 1896 gained control of the Democratic party and nominated William Jennings Bryan for the presidency with the free coinage of silver as the paramount issue. This campaign marked the high tide of agrarian challenge to business men's control of the government.

After the defeat of Bryan agrarian discontent abated somewhat because of a period of relative prosperity for western and southern agriculturalists. But it was merely an abatement. Bryan returned to the attack in 1900 only to meet a more decisive defeat than in 1896. During the Roosevelt, Taft and Wilson administrations, 1901-21, there was no agrarian party in national politics, but there were a number of congressmen in both parties, mainly western Republicans, who were ever on the alert for the interests of their constituents. This group came to be designated as the "Agricultural Bloc," and exercised considerable influence, especially during the administrations of Roosevelt and Wilson. As far back as the seventies and eighties, a good deal of agrarian complaint had been made against the unfair practices of railroads and manufacturing corporations that held a more or less monopolistic position and were loosely designated as "trusts." The so-called "Granger movement" and certain local "anti-monopoly" parties had endeavored to bring railroads and trusts under state regulation and had succeeded to some extent. But since trusts and railroads were interstate in character, any regulation to be effective had to be national in scope. In 1890 Congress had made a feeble effort to prohibit trusts, and in 1887 had attempted to regulate railroads, but almost nothing of importance had been accomplished. In the first decade and a half of the twentieth century the agrarians renewed their efforts and obtained the support of the presidents. Many regulatory laws were passed and a number of suits against the trusts were successfully prosecuted. During President Wilson's administration Federal Land Banks were established which made it possible for farmers to obtain long term loans at lower interest rates than had ever been the case before.

During the World War high prices for agricultural products gave rise to excessive inflation of agricultural land values, particularly in the grain and meat producing regions of the West. When the prices of agricultural products

began to return to their pre-war level, those who had purchased at high prices and even those owners who had retained their land throughout the war suffered greatly, for prices of other products did not decrease as rapidly. Consequently agitation began for some sort of agricultural relief for the growers of staples, the outcome of which was the introduction in Congress of the McNary-Haugen Bill. The ostensible purposes of the bill were to promote orderly marketing, provide for disposition of surpluses, stabilize prices, minimize speculation and encourage cooperative marketing by producers. The bill passed Congress in 1927 and in modified form again in 1928, but it was vetoed by President Coolidge in both forms. His position was that it discriminated in favor of certain agricultural products against others, that it was in essence a price fixing measure and consequently contrary to sound economic practice. No provision was made directly for stabilization of prices under the Agricultural Marketing Act of 1929. But the Federal Farm Board was authorized to extend credits to cooperative associations whose most important function is the regularization of the flow of products to market and the control of price fluctuations.

VII. LATIN AMERICA. Well developed systems of land tenure existed in America long before the advent of Europeans. Although many of the Indians were primarily hunters or fishermen, having little interest in permanent land rights, such agricultural people as the Nahuas of the Mexican plateau, the Mayas of Yucatan and the inhabitants of the Inca Empire had recognized the need for orderly methods of holding the land and had devised complete agrarian systems. The basic form of tenure was communal; the land belonged to a group (either the members of a kinship unit or the duly recognized residents of a community), was inalienable and was distributed periodically among those entitled to its use. In some regions the distribution was annual, in others only occasional, as parcels of land became available for reallocation or as newly constituted

households required additional plots. In Mexico the group holding the land was the *calpulli*; in the Inca Empire it was the *ayllu*; both of these terms apparently originally signifying kinship units (clans), but both seeming to have become place units (village communities) as the groups became sedentary. Mexican society had advanced partially out of the communal stage and certain lands had become virtually private property before European invasion.

The Spanish conquest tended to preserve rather than to destroy these aboriginal agrarian systems. Society in Spain was still organized somewhat on the feudal basis, and the newly acquired territories were distributed among the conquistadors in large grants which in time became permanent and upon which the natives became peasants or serfs. The *encomiendas* or *repartimientos*, as these grants were called, generally allowed the Indians to retain their own method of holding their parcels of land within the great property. Thus a system of latifundia was imposed upon the system already existing without greatly disturbing the original order, and there developed a dual tenure of land by which the Indian village retained its rights to the communal holdings and the grantee became the overlord of the entire estate. In those parts of Latin America where aboriginal agriculturists existed these two systems survive to the present time almost unchanged.

Many attempts have been made to reform this semi-feudal system. Since most of the estates were held by European-born Spaniards during the colonial period, it was the landless creoles and mestizos and the Indian serfs who most stoutly demanded modification. Some historians consider that it was more against this system of land tenure, with its concomitant social, economic and political inequality, than against the rule by the mother country that the colonies of Spain revolted. Certainly the great unrest which made the revolutions possible was due in large part to the agrarian situation. Little, however, was accomplished toward land reform by the wars for independence, for the new rulers of the country (the creoles and the mestizos) merely replaced the Spaniards as the landholding class. Since independence, frequent efforts have been made to correct the evils of the inherited land system. Such attempts have been usually directed against the monopolization of land with its accompanying evil of peonage, against the communal character of the Indian holdings and

against the great accumulation of landed property by the church. Within a few years after the revolutionary wars, most of the Spanish American republics abolished the ancient institution of *mayorazgos* (entailed estates), following the lead of the government established in Spain by the constitution of 1812. This move permitted the breaking up of vast properties which had been held intact for generations, although family pride in the ancestral estates prevented the accomplishment of all that was desired. In some of the countries, particularly in Argentina, changed economic conditions have hastened the division of many large properties. One of the principal aims of the reform movement of Juárez in Mexico and of the revolution of 1910 in the same country was the abolition of the haciendas or at least a reduction in their size. In Chile, where most of the land is held in extensive estates, measures have been proposed looking toward the decentralization of landed property. Several Latin American countries, notably Argentina, Paraguay and Chile, have also enacted homestead laws making possible the creation of many small farms out of the national domain. Unfortunately these homestead measures came too late to accomplish what similar laws achieved in the settlement of western United States.

Against the accumulation of land in the possession of ecclesiastical organizations many measures have been enacted. This movement, begun by Spain in 1767 when the vast holdings of the Jesuits were confiscated, and continued in 1813 and 1836 when properties of the Inquisition and of religious orders were taken over by the state, extended to the new republics, notably Mexico, where it has been estimated that not less than half of the real estate in the country belonged to the clergy. Here all ecclesiastical property was finally nationalized by the government of Juárez in 1859, to be disposed of to individuals.

Efforts to abolish the aboriginal communal system of tenure have been made in most of the countries where it existed. In 1866 Bolivia declared the Indian agrarian communities abolished and their lands awarded in severalty to the individuals composing the villages. This measure, however, had little effect, since many of the communities completely ignored the law and continued to hold their land as before. The communal tenure of lands was abolished in Mexico by the constitution of 1857 and many of the village lands (*ejidos*) passed into the pcs-

session of large haciendas. Similar attempts to destroy the communal system were made in Ecuador and Peru, but in these countries much of the land is still held in this ancient manner.

It is in Mexico that recent agrarian reform has been most far reaching. Here perhaps more than anywhere else were the evils of the old systems notorious. It has been estimated that in 1910 2 percent of the population owned over 70 percent of the land, and that from 80 to 90 percent of the rural population was landless in the various states of the republic. Furthermore the problem was made acute by the small amount of arable land (about 6 percent of the total), by the diverse racial elements in the population and by the proximity of the United States, where a far more democratic system of land tenure was in practise. After repeated efforts at reform had failed, the unrest finally found expression in the so-called "Agrarian Revolution" of 1910 and following years. This movement was begun, like most revolutions in Latin America, by the upper class political leaders, with such slogans as "Effective Suffrage," "No Reelection," "Mexico for the Mexicans"; but it soon assumed the character of a popular uprising against a method of land tenure to which the people ascribed most of their social, economic and political ills. After the first few destructive years the leaders accepted the popular demand for land as the principal aim of the revolution and the movement settled down to a determined program of agrarian reform.

By this revolution much has been accomplished. Large areas of public domain which had been alienated in great concessions were regained for the nation; both national and state measures were enacted looking toward the breaking up of the large haciendas; greater efforts were made to prevent the accumulation of real estate by religious organizations; and some 4000 villages have been given land, either having their *ejidos* restored or being provided with new holdings of a similar character. Altogether, over 8,000,000 acres have been added to the holdings of villages, mainly at the expense of adjoining large farms. While this last achievement marks a reversal of the Juárez policy of doing away with communal holdings, it seems to offer the only method of protecting the possessions of the large Indian element in the population, unaccustomed as they are to any other system of tenure. It is considered a temporary expedient which will serve until the

Indians become used to modern conception of individual ownership of land. Some attempt has already been made to allot these communal lands in severalty. In the execution of this program of agrarian reform there have been many irregularities and abuses. Some large properties have merely changed hands. Haciendas have been seized with little semblance of justice. Many despoiled landowners despair of obtaining compensation even in the form of bonds of doubtful value. Some officials have grown rich overnight. Although the reform has not yet become so well established as to assure its permanence, it seems on the whole to have accomplished much of lasting benefit to the social, economic and political life of Mexico.

In general Latin America has been slow to abandon the mediaeval institutions of land tenure brought from Spain or the communal system of the aborigines. Increased contact with the modern world, however, the development of industry and commerce, with the greater independence of labor which they bring, and the education of the masses all tend to break down these ancient institutions or to bring about that condition of discontent which has led to agrarian reform in other countries.

AGRARIAN PARTIES. See AGRARIAN MOVEMENTS; PARTIES, POLITICAL.

AGRARIAN SYNDICALISM is a movement for the protection and advancement of agricultural interests. These ends it attempts to achieve through the organization of all agriculturists into federations or unions which foster cooperation in production, distribution or purchase of supplies, or which in some cases attempt to advance agrarian interests by parliamentary methods. Modern agrarian syndicalism originated in France, and is strongest in France and Italy. It is rooted in the long tradition of the struggle of the people attached to the soil against the aggressions of other classes.

In Germany and Austria the parliamentary battle for the defense of agricultural interests has been waged by organized political parties, whereas strictly commercial interests have been promoted by highly specialized cooperative organizations. In France and Spain, where the cooperative movement has taken root more slowly, agrarian syndicalism has assumed the role of political and commercial defender against outside encroachments, and has also become an organ of entente between the diverse elements which compete in production within the agricultural profession itself—especially proprietors and laborers.

A small local syndicate in France or Spain may function as a cooperative for collective production and merchandising of any farm product or for collective purchase and distribution of any materials required in farm production. But as a rule a syndicate of provincial, regional or state proportions relegates specific functions to specialized, subordinate groups among its membership. Such a centralized syndicate acts as the pivot of group activity, coordinates the whole movement and gives the needed direction. As part of the same movement, each cooperative occupies itself with some specialized (usually commercial) phase of that movement.

French syndicalism, as typified by the Central

Union of Syndicates of Agriculture of France, is militant in the fields of politics and jurisprudence, is an agent of rural uplift in the social life of the farmer, and attempts to protect the farmer against fraud and profiteering. Collective production and sale, on the other hand, have been left almost entirely to the functioning of cooperatives.

In Italy the Fascist doctrine has affirmed that professional unity is the basis of every economic-social action; but syndical liberty is limited in the interest of the state. The development of the Italian Federation of Agricultural Syndicates has therefore been more along commercial than political lines, and large scale enterprises have been organized as, for example, the establishment of a fleet to transport phosphate from North Africa. Another variation is found in the land holding and operating syndicates—the *affittanze collettive*. This literally means "collective lease," but is now applied to any association which undertakes the joint management of land, regardless of the form of agreement. These societies vary greatly in different parts of Italy, adapting themselves to whatever method of obtaining and occupying land is in vogue in the respective districts in which they are organized. In the north of Italy farms are acquired and operated as a whole (*a conduzione unita*) on a share or cash rental basis, according to local custom. The society assumes the functions of the farmer, providing the necessary capital and taking the risks. At the same time the labor is performed by the members of the society themselves. Collective farms arose almost everywhere in Sicily as an outcome of the activities of leagues of defense of farm laborers in their struggle for the highest possible return for their labor. Groups of laborers complemented resistance and strike as weapons in their economic struggle by collectively assuming the direction and risk of production. Often the laborers desire to possess a piece of land on which they can cultivate produce for their own subsistence, and after a farm has been acquired jointly it may be subdivided among individual members (*a conduzione divisa*).

Agrarian syndicalism in Spain has recently been extended to embrace colonies settling on the various catch basins in connection with hydrographic developments.

Before the World War two forms of collective organization were common in Russia, the *artel* (*q.v.*) and the *mir* (*q.v.*). The Soviet government has fostered both of these forms, the principles

of which have survived in the collectively operated land holdings (*kolkhoz*) and the communistic rural combines (*komkhoz*). The present aim is to increase farm production by means of these and similar agencies, which shall turn over their marketable surpluses to government agencies for distribution. The government has organized tractor and other machine bases to modernize the mechanical technique of production. Plant breeding stations are to supply improved seeds. Chains of government operated elevators are to handle the products.

The International Agricultural Syndicate embraces national federations of agricultural syndicates or, failing such, federations which effectively represent the vocational interests of farmers. The International Syndicate takes its stand on the defense of the vocational, moral, social and economic interests of agriculturists by means of the dissemination of information and the encouragement of all enterprises associated with farming. The syndicate, originally designed to embrace the states belonging to the League of Nations, has developed to world wide proportions.

AGREEMENT OF THE PEOPLE. This term was applied to a document containing proposed provisions of a new constitution for England, which originated in the group known as Levellers. It was finally laid before the House

of Commons by a council of the officers of the army just before the trial of Charles I, but was never acted upon by that body. The Agreement was the first proposal ever advanced for a written constitution based on the authority of the people of England. It was sponsored by a party unable to accept the ancient form of government by king, lords and commons, but equally distrustful of the unrepresentative remnant of the Long Parliament then sitting at Westminster, and fearful of a government of mere force by the army. This party advocated instead a system of representative government defined in a fundamental document unchangeable by the legislature and in theory resting on the consent of the people, who were expected to subscribe to it.

Agitation for such a solution of the constitutional problem began in the army as early as 1647, and the central principle appears still earlier in some of the pamphlets of John Lilburne, who was the leading spirit among the Levellers. The immediate cause of the document itself, however, was the distrust of both king and Parliament aroused by the negotiations carried on with the Scots by the Presbyterian leaders in the Commons looking toward a restoration of the king without effective safeguards for the security and payment of the soldiers who had fought on the parliamentary side.

On August 1, 1647, the army presented to the king the "Heads of the Proposals," providing for a monarchy limited by law, but his fatuous belief that he could conquer his enemies by dividing them brought to nothing all such attempts at compromise. Meanwhile long discussions of the constitutional question were being held in the council of the army and on October 28, 1647, the Levellers presented to it their solution of the problem, "An Agreement of the People for a firm and present peace upon grounds of common right" (printed in Gardiner's *History of the Great Civil War*, vol. iii, appendix).

The failure of all attempts at compromise brought on the second civil war, which ended in the complete collapse of the royalist cause at Preston in August, 1648. Notwithstanding this defeat of the king the Presbyterian Commons continued to treat with him, and in September they came to an agreement with him for his restoration without guarantees either for the army or for "tender consciences." In desperation the army seized London, drove the Presbyterian members from the House, and

thus compelled the remaining members to hasten the trial of the king. In the midst of these troubles a revised and much enlarged "Agreement of the People" formulated by the Levellers was debated by a council of the officers of the army, agreed to on January 15, 1649, submitted to the Commons on the 20th, and there allowed to die a natural death.

The most important principle of the Agreement (printed in Gardiner's *Constitutional Documents*, p. 270-82) is the assertion that all powers of government are derived by delegation from the people alone. The first form of the document contains more prohibitions than delegations of power, and in this respect is more nearly analogous to the bills of rights than to the frames of government in the later American constitutions. It is interesting to note that both the 1647 and 1649 versions of the Agreement give to the government all powers not reserved to the people either expressly or by implication, the converse of the principle of enumerated powers in the American Federal Constitution.

The "Heads of the Proposals" had included a demand for the distribution of parliamentary seats "according to some rule of equality or proportion," and this general principle was made specific in the Agreement of 1649, which included elaborate provisions for representation of the English and Welsh counties and the more important cities and boroughs, but omitted the rotten boroughs. This was accompanied by provisions for a uniform right of suffrage for all resident "housekeepers" twenty-one years of age and over, with few exceptions besides the adherents of the king. Many of these electoral reforms, as well as other principles of the Agreement, were put in practice later under the Commonwealth and Protectorate and even extended to Scotland and Ireland. All such reforms, however, disappeared in 1660, not to return until the passage of the reform bills of the nineteenth century.

The Agreement of 1647 declared that "matters of religion and the ways of God's worship are not entrusted by us to any human power," although "the public way of instruction" was referred to the discretion of the representatives of the nation. In the 1649 version freedom of conscience was guaranteed to all "such as profess faith in God by Jesus Christ," but with the proviso that "it is not intended to be hereby provided that this liberty shall necessarily extend to Popery or Prelacy."

Other matters scarcely less important were included among these "native rights" of the people of England, but the chief significance of the Agreement as a whole lies in the fact that some of these rights are withheld from the government by the document itself. These prohibitions on the representatives and some of the positive provisions embodied in the Agreement are alike made fundamental and unchangeable. It was a serious defect that no mode of change by the people themselves was provided and that no definite provision was made even for the means whereby the instrument was to be put into effect in the first instance. However, the chance of success even for a more perfect plan was very slight at such a time. The great importance of the Agreement is not in its influence on English institutional development but rather in the place it holds in the growth of ideas, the later effects of which are to be found mainly in America and on the continent of Europe.

Hill (London 1894), and *Adoption and Amendment of Constitutions in Europe and America*, tr. by C. D. Hazen (New York 1895); Pease, T. C., *The Leveller Movement* (Washington 1916); Gooch, G. P., *English Democratic Ideas in the Seventeenth Century*, 2nd edition ed. by H. J. Laski (Cambridge, Eng. 1927).

AGREEMENTS, INTERNATIONAL, are contracts between states which are in most cases expressed in treaties, conventions, protocols and other such formal or informal documents. In general an international agreement is the under-

taking of an obligation by competent authorities and, because systems of government have been autocratic, the competent authorities are usually conceived as "heads of states" or governments as distinct from peoples. The contracting parties are therefore usually referred to as "high." There is, however, a tendency in many nations toward increasing the share in government of all sane adults—a tendency called democratic—and therefore the parties to international agreements are in some cases the "peoples" whose instruments or agents are the governments or heads of states. Moral responsibility for fulfilling the contracts rests upon those who have the actual power, whether the "people," or that small group which in most cases has an effectual influence, or the actual rulers in any state. The agreements, being between states, that is to say, persons in a political relationship, do not affect citizens taken separately, and are morally binding apart from changes of the system of government until the contracting state disappears.

The present system of agreements began about the sixteenth century, although personal agreements, similar to commercial or marital contracts, were made by rulers in all ages. The present state system, however, grew up under the influence of the theory of sovereignty, which used to imply in external affairs the moral isolation of each state and the absence of any responsibility on the part of each ruler or government in regard to other peoples, rulers or governments. International agreements were therefore once supposed to depend for their binding force upon the free choice of the parties, which obscurely implied that they had no binding force at all. The fantastic atomism of this conception was corrected by the early jurists who sought in a "law of nature" some explanation of the fact that sovereigns did appear occasionally to keep their word. Personification of the state, however, which omitted the major characteristic of personality, namely, moral responsibility, weakened the binding force of agreements; and the mythology connected with the actual exercise of power obscured the responsibility of those who held power. It has, nevertheless, always been obvious that international agreements would be useless unless most of them were in practise binding, and at no time have men been deficient in the feeling that their promise had some force to restrain their future acts. On such experience have depended the growth in the number of

international agreements and the criterion of the subject matter they cover.

Limitations of the operation of agreements exist if the contracting parties have already made other agreements on principles invalidating certain kinds of obligation. For example, the Covenant of the League of Nations in regard to the registration of treaties, and the Pact for the renunciation of war "as an instrument of national policy," are believed to invalidate secret military agreements and all treaties following wars whose terms are enforced. It is assumed in all cases that no agreements are valid which include obligations to do immoral acts. Secondly, the phrase *rebus sic stantibus* expresses the limitation understood in the case of agreements, that is to say, that circumstances must remain fundamentally the same if the obligation undertaken is to be morally operative. Whether a revolutionary change leaves the circumstances fundamentally the same is questionable, but in practise some approach of one party to the other is understood to be necessary before the circumstances can be regarded without prejudice as having changed fundamentally. An agreement is not morally inoperative if it is repudiated by only one party to it. Again, an agreement entered into under duress is not a real agreement, because one party is not free to choose. Conventionally, hitherto, since war was regarded as a legal method of deciding issues, obligations undertaken after defeat have been regarded as binding, but international morality seems to have developed almost as far as to imply the absurdity of this even in international law. Again, agreements may be rendered void by later agreements or by later statements of international law; or they may expire on the dissolution of a state party to the agreement; or they may be repudiated by one party if violated by the other; or they may contain express provisions as to the duration of the agreements.

The number of international agreements now operative is said to be about 25,000 (see Myers, D. P., "The Control of Foreign Relations" in *American Political Science Review*, vol. xi, 1917, 24-58). Up to June 30, 1928, 1765 agreements were registered under Article 18 of the Covenant of the League of Nations. These agreements may be roughly classified so as to show what services the state system now provides. First, there are lawmaking treaties, declarations, etc., which express or modify existing customary rules of interstate inter-

course, which are the basis of international law. The Geneva "Red Cross" Conventions of 1864 and 1906, and the Final Act of the Hague Conference, 1899, are examples of lawmaking agreements which affect the future actions of the signatories. Some such agreements, however, express new rights acknowledged universally, as, for example, the Treaties of London of 1881 and 1889 with respect to the neutrality of Belgium, and the Minorities Clauses of the Treaties of 1919 and 1920 with respect to Poland, Rumania, etc. Secondly, all agreements which are not lawmaking may be subdivided into (a) those which envisage war or all the results of war, e.g. treaties of peace, alliance, guarantee, neutrality, etc.; (b) "economic" agreements either in matters of commerce, transport, property, etc., or in matters of employment and labor; and (c) agreements with regard to public health or the promotion of scientific or educational activities. These three divisions correspond to the three classes of services performed by modern government. The agreements under each heading are therefore means by which each state performs its services for its own citizens and subjects, by cooperation with other states. Inevitably each state thus performs services for those who are not its own citizens or subjects but are within the jurisdiction of the other state or states parties to the agreements. This implies the existence of a state system such that no state can now reasonably be conceived as a segregate world, in the original theory of sovereignty. If sovereignty, however, means only the responsibility of an autonomous unit in a social whole, then the word has some applicability.

Agreements, commercial or other, are entered into by private groups of persons who are under the jurisdiction of different states (international combines, shipping "conferences," etc.), and these create an international atmosphere within which government is compelled to operate internationally. But the interdependence of different governmental systems, which is expressed in agreements, delimits the competence of the instruments of government (assemblies, parliaments, etc.) within any state—the state in an agreement remaining a unit, whether its unity is expressed by the executive or by some power of its legislature. In Great Britain the crown expresses the unity of the system of government; in other countries written constitutions define the instrument of interstate intercourse, as in the United States, where the president, but only

with the consent of the Senate (Article 2 of the Constitution), is the instrument. Legislation to make obligations undertaken by agreement operative within any state, is limited by the terms of the interstate relationship. A new type of agreement, however, sets up organs to which states transfer the performance of certain tasks (e.g. the International Commission of the Danube), and such organs, as well as the states, may make agreements. Thus it is believed that the League can, in international law, become a party to a treaty, although this has not so far occurred.

The nature of international agreements has obviously been undergoing rapid development in recent years, and the state system now tends to produce new administrative interlocking of specialized departments for commerce, labor, etc., which are in relationship across frontiers, independently of foreign offices and the old diplomatic system. Thus states no longer are in contact only at one point in their "circumference," but interpenetrate administratively. International agreements, like municipal law, are tending to be not prohibitions or protections but contracts of cooperation in common tasks.

AGRICOLA (Latinization of Georg Bauer) (1494-1555), physician, natural scientist and father of the written technology of mining and metallurgy. He was born at Glauchau, Saxony, graduated from the University of Leipsic, and taught Latin and Greek at the Municipal School of Zwickau, later being principal there. In 1522 he went to lecture at Leipsic. He spent the years 1524-26 in studying philosophy, medicine and natural sciences in Italy. In 1527 he became town physician of Joachimsthal, a rapidly growing mining town in Bohemia founded eleven years before. He spent his leisure in visiting the mines and smelters, in reading all

the Greek and Latin literature he could find on the subject of minerals and mining, and in acquiring knowledge from the more intelligent of the skilled workmen. He also purchased a share in a profitable mine, resigned his position as physician, and spent two or three more years in travel and study. In 1533 he became city physician at Chemnitz, a famous mining town in Saxony, and lived there until his death in 1555. Columella's treatise *De re rustica*, which reached its fifteenth or sixteenth edition before Agricola died, inspired him to attempt a service to the mineral industry similar to that Columella had rendered to agriculture. In 1530 he published *Bermannus* (Basel 1530), written in dialogue form and correlating the minerals mentioned by the ancients with those found in the Saxon mines, and in 1546 the first work on physical geology, *De ortu et causis subterraneorum* (Basel 1546), in a volume containing *De natura eorum quae effluunt ex terra* (Subterranean Waters and Gases). He also wrote *De natura fossilium*, the first systematic work on mineralogy; *De veteribus et novis metallis*, chiefly a history of metals; and *Interpretatio germanica vocum rei metallica*, a glossary of Latin and German mineralogical and metallurgical terms. His masterpiece *De re metallica* (Basel 1556) appeared after his death. This work in twelve books, freely illustrated, covers the whole range of mining and metallurgical science as known to him. It passed through ten editions in three foreign languages, and for two centuries remained the best work on the subject. It was an immense advance over anything that had previously appeared; for, instead of following the speculative methods of the Greeks, it is based on accurate observation. Herbert C. Hoover, who made the only English translation of it (London 1912), unhesitatingly says that Agricola's ideas on the origin of ore deposits are much sounder than those of Werner whose writings, 250 years later, are generally regarded as the foundation of economic geology. Agricola was a contemporary of Paracelsus and deserves a much higher place in the history of science than the latter, although his works have received much less attention, probably because miners and metallurgists pay great attention to improvements in technology and but little to its history. The importance of his contribution to the building up of a sound technology of the mineral industry can hardly be overemphasized. He was probably one of the greatest factors in bringing about the industrial revolution in

Europe through converting into applied science the empirical practises then used in the production of metals. In addition to doing his scholarly work he was active in public life in Chemnitz and held many offices there.

AGRICULTURAL COLONIES. *See* LAND SETTLEMENT.

AGRICULTURAL COOPERATION.

GENERAL. Broadly understood, agricultural cooperation represents the application of cooperative principles to the needs of the agricultural population. Agricultural cooperation as thus interpreted has as many subdivisions as there are distinct economic interests which can be promoted by combined action. So interpreted, agricultural cooperation cuts across the usual functional classification of cooperative forms. However, the more useful notion of agricultural cooperation is much narrower; it is limited to those varieties of cooperative effort which serve the needs of the agriculturist as one engaged in the farming business. Generally speaking, the contacts of an agricultural enterprise with the outside world center about the borrowing of capital funds, the purchase of equipment, materials and supplies as well as of services incidental to the basic production process, and the disposition of the product. Ordinarily, therefore, agricultural cooperation comprises rural credit cooperation, cooperative purchasing of farm equipment and supplies, and cooperative processing and marketing of products.

The nature of services rendered and the type of members served give a clue to the distinctive characteristic of agricultural cooperation as a movement. It is the only important branch of cooperation resting upon a large mass of small business units as a base. Only in agriculture has the small scale producer shown ability to survive competition with larger units, and only in agriculture has it been possible to utilize cooperative principles for the promotion of busi-

ness efficiency. The paradox of a cooperative movement with a business membership is more apparent than real. It is just because the farmer realizes his inadequacy as a business man that he seeks the help of a cooperative which will relieve him of many of the important business duties otherwise so difficult and burdensome.

However, the business character of the membership leaves its peculiar impress on the movement. The ties between the members and the organization are not as many sided or as durable as are found in labor cooperation. The much talked of individualism of the farmer, often indistinguishable from the assertive independence of the petty business man, makes it hard to induce him to join a cooperative and to keep him actively interested once he has been enrolled. On the other hand the gross receipts per member, and hence the capitalization, of an agricultural association are far larger than in other forms of cooperation. It is not surprising therefore that general principles of cooperation are modified in several ways when they are applied to agriculture. The "one-man-one-vote" rule is adhered to quite generally, although the voting power is frequently proportioned to the amount of business furnished by each member and in some cases voting by proxy is allowed. Moreover agricultural cooperatives are generally open to new recruits from among the farmers. However, capital is often attracted at the cost of paying market rates of interest on members' shares and of permitting the ownership of more than one share. Also, in order to mitigate the depressing effect of competition on prices, members are not allowed to leave the organization when it is temporarily advantageous, although they may usually leave at stated intervals. It is significant that the instrumentalities employed in effecting these desirable results are not so much an appeal to the solidarity of interests as the tangible weapon of greater returns. Enforceable contracts are of real, although incidental, help in holding members together.

The real mission of agricultural cooperation is not to bring about a fundamental reconstruction of the business regime but rather to save the farmer from the disabilities entailed by the small size of his business and his lack of training in the ways of a commercial civilization. To accomplish this it must not merely supply all the needed services at reasonable prices but must also attempt to "rationalize" the production side of its members' business. Within lim-

its the farmer must be taught what and how much to produce, what is the best equipment to use and what occasions warrant the borrowing of fresh capital. In this as in its other activities agricultural cooperation may expect assistance from the state, because it attempts not to displace but merely to perfect the existing economic order. The comparative generosity of state aid is another feature which sets it apart from other forms of cooperation.

Conditions for the development of modern cooperation in agriculture were being prepared when the commercialization of economic life began to impinge upon the small agricultural producer. As business has grown and increasingly larger units have developed during the nineteenth century, the situation has become continually more precarious for the small, peasantlike proprietors who, with unbusinesslike methods, have waged an unequal struggle against the towns. The towns first of all absorbed the industries which had been closely associated with farming. Next they developed business men and sales organizations which as bargainers were more than a match for the small farmers. This meant that the farmers were hopelessly at a disadvantage in the struggle to hold their own. In certain countries, notably England, a larger and more aggressive type of farmer got control of the land and was able for a time to meet the business world on its own grounds. On the continent, especially in such countries as Switzerland, Austria, Germany, France and Italy, the struggle of the small farmer was a real one, often a tragedy. It was in these countries that cooperation among farmers first flourished.

So far as is known, the first instance of modern agricultural cooperation occurred in Switzerland, beginning in 1815. This was a cheese making enterprise at Kiesen, and consisted merely of a group of dairymen banded together on the basis of turning the milk into cheese, each man being left with his cheese to dispose of as best he could. This plan was subsequently adapted to all manner of undertakings connected with the processing of agricultural products for the market. Another less common form of this type of quasi-productive cooperation is the cooperative ownership of implements and machines. There are many instances of this among the small farmers on the continent, but very few in England and the United States, a disparity which is partly due to the relatively large size of the English and

American farm. Because of the individualism of the farmer, cooperative ownership of machines is restricted to small farms, for which it seems an essential condition of survival. For the same reason there are only rare cases of collective cultivation of the soil. With the exception of a few instances in Italy and Russia, which are the result of peculiar circumstances, one would search in vain for genuine examples of cooperative farming.

Neither from the manufacture of raw products into a commodity demanded by the market nor from the ownership of equipment was the principle of cooperation carried over into the field of agricultural production proper. Instead the principle was applied with considerable success at the opposite end of the farming business, the point at which the farmer comes into contact with the market, in the sale of his products and in the purchase of his supplies. In the first of these, at least, cooperation has succeeded so well that it surpasses in importance the earlier form from which it sprang—the processing of farm commodities for consumption. Indeed processing at present is undertaken only in combination with marketing.

Cooperative marketing serves a well defined need. Even before the days of high pressure salesmanship, the farmer could not be as efficient in disposing of his produce as those who were engaged in selling as a special business. He is not fully conversant with market opportunities, nor is he always cognizant of the precise shape and form in which his produce may be wanted. Even if he is in possession of all the relevant information, it may be uneconomical for him, because of the relatively small sales of any specific item, to bring his product to the best market or to put it in the form wanted. To take butter as an example: the best of cream may be produced on almost any good dairy farm, but to turn this cream into butter requires hundreds of dollars' worth of equipment, unless primitive and expensive hand methods are used. To market the butter from an individual farm is either not feasible at all, or, at best expensive. The farmer is therefore forced to leave a large part of his marketing to an agent, either a merchant or a cooperative company of which he is a member.

In its marketing phase, perhaps more than in any other, agricultural cooperation differs from what is ordinarily understood by cooperation. As an organization a marketing association adopts the form of a business concern

with a variety of security issues arranged so as to preserve the equitable distribution of control between members and to allow for considerable borrowing of funds from the outside. Its dealings with members are not unlike those of a commission house which makes a settlement with its customers on the basis of price received for the produce less the commission charge for handling it. The important differences are, first, the limitation of its services to members, although even this is not always the case, and second, the way in which the cost of handling is computed. While the charges of the commission house bear no apparent relation to the expenses incurred by the house, those of a non-profit making cooperative must obviously be based on cost. The way in which expenses incurred are transmuted into deductions from gross receipts varies according as each member's produce is handled independently or is pooled with that of other members. The method of settlement with members is also affected by the length of time for which the produce is pooled, that is, whether it is intended for immediate sale or is to be manipulated by the cooperative for the length of perhaps an entire season in the hope of selling it at the best possible price. The "manipulation pool" gains in importance with the development of "commodity marketing," which attempts to control a sufficiently large stock of a single commodity to insure a real influence in the market. Obviously an organization of this type differs also from an ordinary commission house in that it must control the disposition of produce by its members; it cannot allow them to sell to other concerns if it is to build up and preserve its position in the market.

A local marketing association can do a great deal for the farmers by pooling their produce, establishing agencies in more distant markets, helping to put the commodity in a marketable form and finally by increasing through combination the bargaining power of its members. The efficiency with which these services are rendered is in direct relation to the size of the organization. The greater the number of individual farmers combined, the less is the expense of handling the produce and the more impressive is the influence exerted by the organization in the market. The advantages of size can be achieved in several ways: small local associations may federate and set up a directing center to which certain important functions may be delegated; or an association may attempt

expansion more directly by increasing its membership and having local branches for immediate contacts; or it may enter into contractual arrangements with other associations for a limited length of time. The method by which an organization overcomes the difficulties involved in the dispersion of its membership depends upon the importance of services which must be performed locally; upon the homogeneity of its potential membership; and finally upon the stage of development which cooperation has reached when an increase in size appears urgent. If strong local associations have grown spontaneously and have been at least moderately successful, if the raising of a particular commodity is in the hands of both large and small producers, if no particular savings can be effected by doing grading, packing and storing on a larger scale than is possible for a local association, then the federation or contract devices are the more practicable methods to adopt. Otherwise a centralized organization is preferable.

Among the best examples of farmers' selling organizations of Europe are the Danish butter and bacon companies. The great share of Danish butter is made in cooperative factories, under state inspection and control so far as quality and grades are concerned. For many years Danish butter has been rated at the top in quality. Its main market is England, to which it is sent through several export federations with agents in England. These butter companies have long been recognized as models of efficiency. Of similar character are the well-known "bacon factories" of Denmark. One of the most significant features of the Danish cooperative bacon companies is their control over production. They do not directly limit the amount of swine which may be delivered, but they do prescribe, within narrow limits, the type and quality. Since the authorities at cooperative headquarters now and then change the margins among grades so as to make it more profitable to send hogs to market at one weight rather than another, they are also in a position to increase or diminish the supply of hogs at the time according as lighter or heavier weight is preferred. Thus the quantity of bacon made during a given season can be appreciably controlled or at least greatly influenced.

While in Denmark and several other countries, such as Ireland and the Netherlands, the marketing associations are the outstanding type of cooperative effort, other European countries

excel in cooperative purchase of supplies wanted by the farmers. Europe as a whole is far in advance of America in cooperative purchasing. Here again it is the small size of the farm which furnishes an essential condition for cooperation. Much as the small farmer is interested in cooperative selling, he is still more concerned with cooperative purchasing. He is often near a good market for sale, such as an open air city market, but finds himself at a hopeless disadvantage in dealing with people from whom he must make purchases. Not only is machinery to be bought, but from year to year it is necessary to buy commercial fertilizers. In these latter purchases there has always been until recently a great chance for fraud, and where fraud was absent there was at least an opportunity for the dealer to take a high margin of profit. The cooperative company has an advantage over many private dealers in being able to buy in large quantities and for an assured market. Again, the cooperative market can render a great service in the matter of credit, first, by encouraging cash payments, and second, by providing credit at cost where it is really needed. On the continent, especially in Germany, cooperative buying is closely associated with credit cooperation of the rural type.

UNITED STATES AND CANADA. In America conditions are quite different from those in Europe. The farms are in the main larger; the farmers are more independent in economic matters and as cooperators they are harder to deal with. Successful cooperation is mainly of the sales type, although in the sections of the country where markets for selling are good, and where agriculture is of such a character as to require heavier purchases of goods needed in the round of production, the buying side is proportionately more in evidence.

Cooperation began in the United States much as in Europe, as a means by which certain small farmers could manufacture dairy products into forms which could be marketed. The first known instance of this was the cooperative making of cheese in the state of Wisconsin in 1841. Cooperation in the manufacture of cheese and butter has grown to great proportions; at first progress was slow, but since 1890 it has been persistent and widespread. Other lines of cooperation began, largely during the seventies, inspired by the Grange.

The occasion of the rapid growth of the Grange was clearly that of a surplus of agri-

cultural produce; the trouble was not merely a weak demand in the ultimate markets but also a serious disorganization in the channels from producers to the market. Lack of grading, involving ignorance on the part of producers of what they were offering for sale; high and unregulated freight rates; middlemen who were able to make wide margins; a wholesale trade so far removed from the farmer and his comprehension of big business as to lead to all manner of suspicions; retailers unregulated by law, without the restraining competition of mail order houses or chain stores—all these combined to produce a multiplicity of both real and imagined grievances among farm people. They were easily induced to form cooperative companies, some of which succeeded, more of which were ill-starred.

While there were sporadic instances of cooperation in the manufacture of cheese and butter before the days of the Grange, and likewise a few efforts at cooperative grain selling, there were but a small number of such undertakings, and these not very important or stable. The Grange was instrumental in launching cooperation in butter and cheese manufacturing, taking these operations, often permanently, out of the home. At the same time grain and livestock shipping companies, or rather groups, were organized. The majority of the cooperative companies were not incorporated, while the rest were incorporated under the general corporation laws. When reverses came, as they were bound to come, the so-called cooperatives either went out of existence or became ordinary business units owned and managed for profit. By this means numerous farmers became business men, left their farms and moved into the villages. In spite of the fact that the Grange was instrumental in starting hundreds of cooperative undertakings, only a few were still in existence by 1880, four years after the beginning of the decline of the Grange. The remaining units were mainly organizations for the purchase of farm and household supplies, and these were located not in the heart of the farming district but in the eastern states.

The Farmers Alliance ran a very similar course in relation to cooperation, organizing and inspiring the organization of a number of companies. The story of their successes and failures is almost the same as that of the Grange period. The majority of the undertakings were in the Southwest and Middle West. They suffered both from the lack of a proper legal

foundation and the lack of intelligent leadership. The alliance itself came virtually to an end in the early nineties. The cooperatives it founded struggled on, with here and there an instance of survival which suggested permanence. This period covers the years from about 1880 to 1892.

In 1902 two farmer movements came to the front: the Farmers Educational and Cooperative Union and the American Society of Equity. Both undertook, more exclusively than had their predecessors, to solve the marketing problem. Both organized local cooperatives, including consumers' societies and selling companies. The Equity and its successor, the Equity Union, went even farther than the local undertakings and established several centralizer creameries, some of which are making over three million pounds of butter per year. Each of these organizations has established local livestock shipping associations, combined later into central livestock exchanges. Central grain exchanges have been attempted. The Farmers Union has established several big and apparently successful exchanges for handling supplies for farmers and their families. It cannot be said that either the union or the Equity has solved the problem of cooperation, yet they have both promoted very important cooperative companies.

The American Farm Bureau Federation, which came into existence in 1919, gave promise of sweeping the cooperative field. Unfortunately its most prominent effort, designed to revolutionize the marketing of grain, came to an untimely and inglorious end. The dairy marketing plans have not been put into practise and are not being pushed. The influence of the Farm Bureau has been important in connection with many marketing undertakings, yet it has not been a revolutionizing force within the field.

Real success in cooperative marketing of agricultural products has been achieved only for a comparatively few commodities, and has been due to those immediately concerned in the operations rather than to outside inspiration. That is not to say that cooperation is of no importance in the sale of some portion of all leading agricultural products. There are co-operatives, local and central, in the marketing of grain; of livestock; of dairy products, including milk, butter and cheese; of fruits and vegetables; of poultry and eggs; of cotton; of tobacco. Approximately 11,000 cooperative marketing companies are doing business at the

present time in the United States; their aggregate membership, including some overlapping, is about 2,000,000. The amount of business done has in some years reached \$2,500,000,000, or not far from a quarter of the annual sales of farm produce. In general these companies are bringing greater returns to the farm than could otherwise be obtained.

The cooperative marketing of fruit offers some of the most conspicuous examples of success. The California Fruit Growers' Exchange stands out as a model in many important particulars. Some forty years ago the citrus growers of southern California found themselves growing fruit for which there did not appear to be a sufficient demand. The prices offered were so low as to result in severe losses to the growers; often the prices would not cover the cost of picking and boxing fruit after it was ripe. As a result of the feeling that local private shipping companies were getting too much for the services rendered, attempts to organize cooperatives were made as early as 1891 and 1892. In 1895 the Southern California Fruit Exchange was organized. This company had many ups and downs, but was able to overcome difficulties sufficiently to keep going. In 1905 the name was changed to California Fruit Growers' Exchange. This organization, with the bulk of the citrus product under its control, has won a respectable place for itself in the business world. Its cost of doing business is remarkably low; its command of the market is as near to perfection as is often reached by any organization not having a monopoly; its return, therefore, to the individual member is such as to commend itself to the great majority of growers.

The company is composed of local associations of growers, twenty-two district exchanges and the central exchange. The locals own and operate packing houses and equipment for handling the fruit. The district exchanges are composed of locals, each local electing one representative to the district board. In turn the central exchange is composed of the districts united through a board, each district furnishing one representative. Sales are made by district managers acting under the advice of the central exchange sales department. Pooling is done through the locals, over lengths of time varying from a month to the full season, as they may agree upon.

The California Fruit Growers' Exchange does the largest business of any single cooperative company of the United States. Its sales in

1927 reached \$85,000,000. Sales are made through agents, usually by auction, in all cities of considerable size. Not infrequently this organization is accused of exercising monopoly control over the orange and lemon trade. This is true only in a very restricted sense. To begin with, it exercises no control over the planting of orchards. Even the supply coming to the market it can regulate only indirectly. The secret of its success lies in the fact that the exchange is in a position to take advantage of market conditions in a way which is open only to big, efficient organizations. It has at hand, almost hourly, complete information in regard to its market, with the aid of which it is able to direct fruit to the places where it is most wanted and away from points where there is a threatened oversupply. Moreover the supply sent is varied on the basis of probable returns, the growers being advised to pick and ship for table use an amount not in excess of a given quantity, the balance to be sent to by-product plants for the manufacture of citrate of lime, lemon oil and the like. As a rule these plants handle only the inferior fruit; however, when prices are low, a correspondingly higher grade will be used in this manner.

The California Fruit Growers' Exchange, together with another much smaller cooperative citrus company of California, markets over 80 percent of the citrus fruit of the state. A large part of the Florida citrus fruit is likewise co-operatively marketed.

The producers of milk, butter and cheese have had real occasion to look for better markets and to demand better marketing facilities and treatment than the commercial companies have afforded.

The dairymen furnishing milk for all the larger cities of the United States are organized into bargaining companies through which agreements with city milk distributors are made. As cities have grown and have had their milk supplied by increasingly larger areas, it has become evident that the individual dairyman was helpless as a bargainer against the highly organized city distributors. The early efforts at organizing the fluid milk dairymen were not very successful. In recent years, however, some forty associations, several of which deal with the distributors of more than one city, have reached a degree of development which promises to be permanent. These associations vary in membership from a few hundred to over fifty thousand. So far the prices are made by

the bargaining parties on the basis of what the market will apparently stand without cutting off the demand or over-stimulating the supply. The prices paid by the distributors of milk have been much higher in relation to butter-fat values since the organization of the cooperative than was formerly the case.

Cheese making is much more localized than the production of butter. This accounts for the earlier efforts on the part of cheese producers to establish a cooperative marketing system. There are two main cooperative companies: the National Cheese Producers' Federation, with headquarters in Wisconsin, and the Tillamook County (Oregon) Creamery Association. These associations undertake to grade and sell the product of the cheese factories which belong to the federations. They are handling about one tenth of the cheese of the country.

Since butter is made in almost every county of the country, the butter producers are a widely scattered group. For many years it was evident that the butter market was in need of reorganization. Apparently the private dealers had made all the progress they were capable of; still they left much to be desired. In 1921 a cooperative association of large proportions and with an ambitious program was launched in Minnesota. This organization, known as the "Land o' Lakes Creameries, Inc.," was not the first attempt of its kind, but at present it is the outstanding instance of the cooperative marketing of butter. Since a large percentage of the creamery butter of the country is made within a few hundred miles of St. Paul, it was logical that this city should become the center of cooperation in the selling of butter. The company comprises between four and five hundred cooperative creameries, over a third of the whole number of such creameries of the three states of Minnesota, Iowa and Wisconsin. It has accomplished remarkable things in the matter of changing the quality of butter, increasing the proportion of the high grades and also increasing the demand for it. Its sales are now approaching the hundred million pound mark, and its receipts are distinctly above the returns available through other channels. The returns are better because the butter is more economically handled, going through fewer hands and being shipped to its destination by more direct routes.

Cooperative grain marketing got under way after the unsuccessful attempts made in the first years of the twentieth century. Over four

thousand elevators were cooperatively owned. These elevators have done well in reducing the local costs of handling grain. They have never been able to federate effectively for handling grain on the central markets or for export. Several states have highly centralized wheat pools, but for the most part their successes have been nominal. In 1929 the Farmers National Grain Corporation was organized to provide a national marketing agency for these pools and local elevators. It has the support of the government and its main purpose is to arrange for the orderly export of grain to relieve the depression in the American market. The organization is still in its incipient stages, so that little of significance can be said of it at present.

In Canada wheat pools have reached great size and have attained a high degree of perfection. They are conducted on the federated plan. In recent years they have handled over half of the wheat, and some of the other grain, sold by the farmers of the western provinces. They conduct an export business, maintaining agencies in the leading foreign markets. These pools, three in number, acting jointly through a central sales agency, do the largest business of any cooperative on the continent; their gross receipts are about twice as large as those of the California Fruit Growers' Exchange.

So far we have dealt with cooperative marketing and with but a few instances of cooperation in the processing of agricultural produce. In America other applications of cooperation to agriculture are few and thus far have not attained great importance. However, we may briefly mention the more important undertakings.

Of these the more specifically agricultural types of cooperation are found in irrigation and insurance. About six and a half million acres, or slightly less than a third of the land under irrigation, are watered by cooperative companies. Irrigation is a process which lends itself quite well to this type of management. In insurance the conspicuous examples of rural cooperation are the numerous farmers' mutual fire insurance companies. In some states, notably Pennsylvania and Iowa, they are statewide in their operations and carry a large share of the risks of this sort. In Michigan the "Gleaners" carry life insurance and fire insurance and also act in a limited manner as a credit society.

The American countryside has had and continues to have many examples of consumers'

cooperation among the farmers, but they are neither successful nor important. Again and again cooperative stores have been started, and while the number of new ones is usually considerable, the whole number hardly increases from year to year. The casualties among them are high, especially in periods of falling prices such as that following the World War. While cooperative stores are successful in Europe, it seems impossible for them to gain a foothold in America, at least while conditions remain the same as at present. Two institutions militate against the cooperative store: the mail order house with its attractive prices and good service, and the chain store with its narrow margins on which the retail work is done.

In concluding we may note some recent developments which point to the disappearance of some of the old problems and the emergence of new tendencies in agricultural cooperation. The early efforts sponsored by the Grange were defeated partly because of the lack of a legal foundation for the work of cooperatives. This has been remedied by state and federal legislation, mostly since 1900. Acts were passed providing for the incorporation of cooperative companies, giving them security and advantages which they could not enjoy under the general corporation laws. The new legislation and court decisions permit organization along Rochdale lines (limitation of shares and distribution of dividends according to patronage), the creation of non-stock associations with net returns settlements, and make the contracts between a marketing association and its members enforceable against the latter by allowing the collection of "liquidated damages" and the use of injunction and specific performance proceedings. Laws have also been passed providing immunity to cooperative companies from antitrust laws in cases where technically the marketing companies appeared to make themselves liable to prosecution.

Related to changes in law is the emergence of governmental support to agricultural cooperation. Nearly all states have departments of markets which almost without exception have facilitated the work of farmer cooperatives. Experiment stations have made a series of studies which have served to furnish information concerning the successes and difficulties attendant upon the workings of cooperative undertakings. The Bureau of Agricultural Economics of the federal Department of Agriculture has a division of cooperation, the purpose of which is

to study and promote the interests of cooperation among farmers. Through the War Finance Corporation and the Intermediate Credit Act the federal government has put money at the disposal of cooperative companies. Finally the new Federal Farm Board has been active in stimulating the organization of national agencies of cooperatives which could undertake a regulated export of agricultural products. The recently organized National Chamber of Agricultural Cooperatives, a combination of marketing cooperatives, is to exert pressure upon the government and public opinion of the country as well as to promote a further increase in membership of these cooperatives.

The recent trends in cooperation are clearly toward larger units. It has been demonstrated again and again that cooperative companies, like other organizations for doing business, cannot hope for success while running on the basis of small output. The cooperative creameries, for example, which were started forty years ago, were designed to accommodate the farmers dependent upon a load hauled over poor roads by horses. Now with good roads and gasoline trucks the sphere of activity may well be four times as extensive. The larger cooperatives of all sorts show the lowest unit costs.

Again, and this is even more significant, cooperative companies in the past have viewed the market as a great stronghold to be attacked and conquered. Now it is evident that any successful attack must be accompanied by organized action respecting the use to be made of the conquered forces. In the early years of cooperation it was taken for granted that the market could absorb all possible production at a remunerative price, if only the predatory characteristics of those guarding access to the market could be subdued. Now it is understood that marketing means taking care that the demand for goods be not demoralized by oversupply. This is the greatest lesson, and one of the hardest for the farmer to learn. In this phase of the subject little progress has been made, but the outlook is hopeful.

AGRICULTURAL CREDIT. Credit for agriculture differs in important particulars from credit for other purposes. First to be noted is the small size of the usual producing unit. From a credit standpoint this means a large number of small loans to administer, approximating consumer's credit in this respect, especially in countries with many small holdings. The greater the number of borrowers among whom a given volume of loans is divided, the better the burden of risk is distributed; but unless each risk is scrutinized carefully, the advantage of such distribution is lost. The small size of the producing unit makes impossible the organization of the enterprise on a corporate basis with limited liability of stock holders, and thus greatly restricts the sources of agricultural credit. Moreover, if a business is large enough to be incorporated, its entrepreneur can ordinarily sell stocks and bonds for most of the capital needed, whereas if it is not large enough to be incorporated, the entrepreneur must ordinarily provide nearly half of the capital himself. A further consequence is that the individual borrower is weak in bargaining for loans.

Next in importance is the close relationship between the business and family affairs. The capital available for any farm business is largely dependent upon the financial status of the family. A farmer with limited resources borrows with difficulty, almost regardless of his managerial ability. A young man in agriculture ordinarily has to wait until he has acquired some capital of his own before he can borrow the additional capital he needs to start even as a share tenant, and even then his operations are likely to be restricted because he cannot obtain capital enough. He must wait until he has acquired much more before he can start as an owner-operator. Hence such matters as age at marriage, size of family, family thrift, standard of living, and desire for education for the family, profoundly affect farming operations through affecting the rate of accumulation of capital and the amount of capital that can be borrowed. In this respect agricultural credit is somewhat similar to credit for retailing and shopkeeping, and in distinct contrast to industrial credit. However, when business and living are closely associated, as in agriculture, owning the business becomes necessary in order to insure a per-

manent home for the family, whereas retailers and shopkeepers are more content to rent their places of business indefinitely, thus reducing their credit needs.

Inheritance also figures in an especially important way in the problem of agricultural financing. The settlement of an agricultural estate ordinarily requires the sale of the property, or at least the writing of a mortgage against it. Each new generation of farmers starts with a new crop of mortgages. In many countries under normal conditions the new mortgages written when estates are passed on have nearly equaled the payments on existing mortgages, so that the total burden of farm mortgage indebtedness in the country has tended to remain about constant. In the United States this process has been greatly disturbed since 1900 by the rapid rise in price levels and land values up to 1920, and the rapid decline in land values since then. In general farmers have made larger payments on their mortgages in the United States than in Europe; but they have also more generally followed the practise of retiring, while still in their early advanced years, to the villages or small cities and selling or renting their farms. The recent depreciation of money greatly reduced for a time the mortgage indebtedness on farms in several countries of Europe.

From the standpoint of the credit agency, the combination of farm business with living makes it difficult to draw the line closely between loans for production and those for consumption purposes. A loan for an automobile is clearly of this confused sort. A loan to build a new farm house cannot be looked upon purely as a consumption loan. In the southern cotton states of the United States a large volume of loans is made to farmers to meet their living expenses while the crop is growing. This practise prevails to a greater or less degree in all regions depending largely on cash crops. With farming so little and so lately removed from a largely self-sufficient condition, farm entrepreneurs are not likely to understand the credit aspects of their businesses or to keep the proper sort of financial records. Many will want loans that are not good risks; but more will not appreciate possible advantageous uses of loans. This places an added responsibility on the loaning agency.

A distinction perhaps should be made between loans for production and loans for marketing, the latter including loans to farmers' cooperative marketing associations or dealers

of various kinds, covering the operations of transportation, storage, processing and merchandising. Marketing loans may be for very short periods covering the time required to move produce through the marketing channels, or for as much as a year or longer to permit the carrying over to another year of produce from a year of large surplus. Marketing loans negotiated by regular middlemen tend to be treated as regular commercial loans.

The self-sufficiency of the farm unit is an important factor in its credit needs. The general drift in agriculture is clearly toward more dependence on the market for household and farming supplies, but it is easy to exaggerate the extent of this movement. Even in the United States, where agriculture has been commercialized as much as anywhere, 20.3 percent of the value of farm production between 1923 and 1928 was food and fuel used by the farm household. Where holdings are small, as in most of Europe and Asia, the farm produces a much larger proportion of the family living, and the marketable surplus of any one farm is very small. These circumstances reduce still further the size of the loan required by the individual farm, and at the same time the amount of cash income available to liquidate loans.

There are a number of important characteristics of agriculture growing out of its close dependence on nature which affect the character of its credit. One of these is the slow turnover of its current operating capital. Frequently the ninety days which is the usual limit for commercial paper is too short a period for the repayment of crop or livestock loans. Sometimes six or even nine months are needed if the selling is not to be hurried. Some loans, however, such as those for feed for milk cows, may be liquidated in thirty days. Another characteristic of agriculture is the low ratio of operating to fixed capital. Perhaps only a few months are needed to mature and harvest a crop, but a large fixed investment in land, buildings, machinery and work stock is required in the first place. Although only a few weeks elapse between the purchase of dairy feed and the receiving of the returns for the milk or cream sold, a large investment is involved in the dairy herd.

A factor of some importance in contrasting agricultural and commercial credit is the device of production by stages. In industry there has developed a vast scheme of separation of the whole manufacturing process into parts or stages which are carried on in separate plants, usually

under more or less separate management. This means that each of these plants needs a loan for only a short period, until it can dispose of its product to some unit next farther along in the process. This development has the effect of shortening the period for which commercial loans need to be made, and of increasing the ratio of the operating to the fixed capital. In agriculture production by stages has developed to a considerable extent in the case of a few products, such as the growing of young animals in grazing regions and the fattening of them in grain areas, but development along these lines has been nowhere as marked as in industry; nor is it likely to proceed very rapidly. In fact more significant at present is the increasing practise of growing feed and keeping livestock on the same farms or ranches.

No doubt the greatest importance of natural factors in the agricultural credit problem is in the element of risk. Estimates of the total crop damages in the United States for the decade from 1909 to 1919 are as follows: wheat, 28.77 percent; corn, 31.99 percent; oats, 24.52 percent; barley, 28.65 percent; flaxseed, 36.44 percent; rice, 19.04 percent; hay, 20.35 percent; potatoes, 30.12 percent; tobacco, 20.35 percent; cotton, 35.49 percent. These data are averages of estimates made by crop reporters and must be understood as subject to an uncertain amount of bias in either direction. The damage results almost entirely from climatic misfortunes and from plant diseases and pests. In individual areas and in individual years it may be much more severe, amounting frequently to complete crop failure, occurring sometimes two or three years in succession. Moreover most of the foregoing forms of crop damage affect a large area at a time, frequently several states. This means that any local institution, such as a local bank or even a Federal Reserve Bank or an Intermediate Credit Bank, may find the security of a large part of its loans affected at one time. If, however, crops are short over most of the area where produced, the price may rise more than sufficiently to offset the reduction in yield. Nevertheless the more usual situation is that the crop will be short or especially short in some part of the area, constituting a real impairment of credit obligations in that section.

Of almost equal importance is the risk that the weather will be so propitious over most of the producing area that prices will be very low. Unusually large acreages may produce the same effect. Not only are many of the farmers unable

to meet their loans fully under such conditions, but they may need to hold their crop until late in the marketing season in order to obtain a price that is reasonable for such a supply. A large crop may glut the marketing channels if it is sold in the usual percentages by months.

The livestock risks are not so great as the crop risks. Seldom are whole herds wiped out by droughts, storms, floods or disease epidemics. Nevertheless enough damage to livestock occurs to make risk a real factor in the problem. Loans on feeder stock take the chance that the price will decline between the dates of purchase and of sale and thus wipe out the margin of gain. However, where the farmer has the feed available, such loans are properly considered good risks.

The hazards described are greater to the banker for the minor than for the major crops, because fluctuations in acreage and yield are proportionately greater. The lesser crops are likely to be more localized and hence all subject to the same weather effects at one time. Risks are greatest in specialized farming areas and cash-crop areas. Combined livestock and crop farming offers fewer hazards than crop farming alone. The close relation between the farm business and family living becomes a factor in risk in that in many cases the family living must first be provided out of the income from crops before any payment can be made on the loans.

Loans on farm real estate have the usual real estate hazards, such as fire and tornado, which can be insured for the most part, and also those of price decline and unusual depreciation from misuse of property. Land values are more subject to "booms" than are building values, because buildings can easily be reproduced at cost. Also, when land values recede they recede over wide areas, as in the whole of the north Atlantic section of the United States from 1880 to 1900. In newer farming areas, as in the northwest states, land values fluctuate somewhat with rainfall periods. The possibilities of exploitative farming add to the hazards of misuse of property in agriculture.

It is sometimes thought that further commercializing and capitalizing of agriculture will greatly change the nature of its financing and remove many of the limitations described. In areas where farms are getting larger and farming less labor-intensive, undoubtedly operating loans are larger and more frequent and somewhat more commercial in character. But changes

in this direction are proceeding slowly at present, even under the unusual influences existing in the United States. No doubt a lack of capital is an important limiting factor in the sections where new systems of farming which require more livestock or machinery are involved. Lack of capital is also preventing the purchase of the larger acreages of land needed. Capital will not flow in readily so long as the basis of the loan is a mortgage on a family farm, even though it be an enlarged family farm—principally for the reason that larger farms mean larger mortgages than are considered good risks. Yet it seems probable that the family farm, enlarged as new conditions require, will continue to be the major basis of operation. Large scale operation in one unit promises to have a real, but after all a limited, development. Chain farming systems—family units under one general supervision—may easily have a more important development. Such organization plans permit corporate organization and sale of stock as a means of raising the fixed capital. Loans for current operations will be larger and somewhat more liquid with such organizations. These developments, however, will occur only in certain regions. Taking the world as a whole, small units will probably continue to prevail and the changes affecting credit will be in the nature of a slow increase in production for the market and an accompanying greater use of banking facilities.

A more promising development for overcoming the limitations of credit for agriculture is that of consolidation of the loans of small units by various types of cooperative and semi-public credit institutions such as have been developed particularly in Europe and the United States. As a basis for discussion of these institutions a more complete analysis of the various credit needs is essential. The customary classification of these needs is threefold: short term, intermediate and long term. In the United States short term credit is ordinarily limited to six months; intermediate credit, to periods of from nine months to three years; and long term credit, to periods of five years or more.

The short term needs for credit are principally for labor, feed, fertilizer, seed, sprays, livestock for feeding purposes, the holding of crops for a market, twine and sacks, boxes, barrels and other containers. The labor needs are conspicuously for the final harvesting operations but also for the planting operations and to a lesser extent for the care of the growing crops. Borrowed funds are also sometimes used in part

to hire the labor that cares for livestock on the range or in the feed lot. As already stated, in some situations loans are made for living expenses while the crop is growing. In general farmers are more likely to meet their regular labor bills than most other expenses out of current receipts. Loans to hire labor for the regular farming operations are often far from liquidating within the period of a short term loan—the labor is often partly upon growing livestock, land improvements and the like. Loans for seed become very important in the case of a few crops, notably wheat, potatoes and garden crops. Such loans are entirely liquidating within three to nine months, if the season is not bad. Fertilizer loans are extremely important in the old cotton states of the United States, and in many sections of the Old World. Most fertilizer applications extend their benefits over more than one crop, and hence loans for such purposes may be only partly liquidating in one season. Where fertilizer is used regularly the carry-over from earlier applications makes up the difference. The only livestock loans that are liquidating within the period of short term loans are those for young cattle, pigs and lambs to go into the feed lot in the autumn, or into pastures in the spring as grazers. Loans for these purposes are ordinarily for six months. In market milk areas milk crops may become the basis of such loans if the farmer has most of the needed feed available. Loans to buy feed are made to farmers who have the livestock but not enough feed or not the proper kind of feed to make a balanced ration. Such loans are highly liquid. Loans to finance the holding of farm products by farmers and others are sufficiently liquid as long as the loan is for an amount safely below any probable price decline, and the products are in safe storage. There is a serious question whether the farmers themselves can be trusted to exercise the best judgment as to when to hold and when to sell; a wide price margin is thus essential. Cooperative organizations may in time exercise better judgment than the farmers acting singly; and the market analysis provided by public agencies may also prove to be of great assistance.

The credit needs commonly placed in the intermediate class are the following: farm buildings, land improvements such as clearing, draining and liming, fencing, farm machinery, work stock, breeding stock, milk cows, and orchards and small fruit stock. Many of these, such as farm buildings, land drainage and orchard stock, especially, are not liquidating within the ac-

cepted period of an intermediate type of loan; and in practise they are often covered by regular real estate mortgages running usually for five years. Farmers frequently expect, however, to be able to repay loans for such purposes within two or three years out of the regular income of the farm, and hence would prefer a shorter instrument than a regular real estate mortgage. Also, many such loans are too small to make a regular real estate mortgage desirable. In many cases the farm already has a mortgage upon it which it may not be possible to enlarge or to supplement with a second mortgage. In practise in the United States farmers are often able to borrow the funds for such purposes at their local banks on notes which they keep on renewing until they are all paid. But this arrangement works badly in a period of credit stringency, such as that following the World War, when a large volume of "frozen credits" is produced. Loans for breeding stock, milk cows, work stock, farm machinery and small fruit stock come much nearer to liquidating within the accepted period of intermediate credit.

Long term land credit is commonly secured by mortgages. In the United States the most usual periods for farm mortgages are still five years and ten years, although an increasing number of them are long term amortization mortgages. In Europe the amortization mortgage is much more common. The practise is also developing of dividing heavy loans into first and second mortgages at different rates of interest. Farms are also frequently bought on a contract to pay at a certain rate, together with interest, until enough has been paid to make a mortgage secure.

The slow turnover of capital in agriculture was early recognized as a difficulty in the handling of agricultural loans by commercial banks. Erick Bollman, an early writer on banking in America, said in 1816: "Banks in farming districts are a nuisance." The farmers in turn complained that the commercial banks did not serve them as well as they did the merchants and frequently opposed them. Some of the early banks made loans to agriculture rather freely, even going so far as to use loans on farm lands as the basis of banknote issues. But trouble followed sooner or later in most cases. In consequence, when the National Banking Act was passed in final form in 1864, national banks were forbidden to take real estate as security for loans. Furthermore the requirement of \$50,000 of capital stock for cities of 6000 or less kept banks

from being formed in the agricultural districts. The farmers got much of their credit from merchants and manufacturers of farm machinery. But state banks began to increase in numbers presently, and in 1900 the National Banking Act was amended to permit banks to organize with only \$25,000 of capital in cities or villages of 3000 or less. Then followed a period of rapid increase in banks, as a result of which even rural communities, except in the South, were well supplied with banking service—frequently too well supplied. But the difficulty of slow turnover of capital remained. The Federal Reserve Act of 1913 was the next important forward step. It made six-month agricultural paper eligible to discount by the Federal Reserve Banks, and allowed member banks to make a limited number of mortgage loans on real estate. The Federal Reserve Board has interpreted its provisions liberally, even accepting six-month loans for the purchase of livestock and farm machinery such as tractors. In some of the agricultural states over half of the discounts in 1918 were on agricultural paper. The evidence is now clear that in 1919 and 1920 the Federal Reserve Banks discounted too large a volume of agricultural paper maturing in six months, an important factor in the credit stringency which developed in 1920–21.

In the meantime the Federal Farm Loan System had been established in 1917, with twelve regional banks and a supplementary system of joint stock land banks, for the purpose of loaning to the farmers on land mortgages for the purchase of land, equipment, livestock or fertilizers, or for erecting buildings or improving land. The mortgages must run for not less than five or more than forty years, and are to be paid on the amortization plan. Bonds are sold to obtain the funds loaned.

Intermediate credit was provided by an additional act in 1923 which established an Intermediate Credit Bank in each of the twelve Federal Farm Loan districts, affiliated in management with the Federal Farm Loan banks, and coordinate with them under the Federal Farm Loan Board in Washington. These banks may purchase or discount notes, debentures or other securities of banks, agricultural credit corporations and cattle loan companies. They make loans directly to cooperative associations but not to individual farmers. The loans must be for not less than six months nor more than three years. The funds are raised chiefly by the sale of short time debentures secured by the

rediscounts. The Act of 1923 also permitted the Federal Reserve Banks to rediscount agricultural paper up to nine months. In 1926 about a sixth as much six to nine month paper as three to six month paper was rediscounted.

In 1927 the Federal Farm Loan System was carrying \$1,825,000,000 of farm mortgages and the life insurance companies \$1,999,000,000, the two together carrying forty percent of the farm mortgage loans of the United States. The business of the Federal Loan System is growing at the rate of about \$100,000,000 a year. The Intermediate Credit Banks have had a very limited growth, the total loans for the five years (1923–27) being \$374,000,000 of direct loans to cooperatives, and \$257,000,000 of rediscounts, almost all of these being loans by credit corporations and livestock loan companies.

The further needs of the agricultural credit system of the United States are loans to tenants to enable them to purchase farms; loans to good farmers in the poorer agricultural districts; the transferring of more intermediate credit from country banks, where it is being carried on notes and renewed as needed, to the intermediate credit system, so that when the next credit stringency comes the country banks will not have so many "frozen loans"; strengthening of the country banks; and provision of credit on better terms for the southern states. The intermediate credit system needs to be more aggressively administered.

The two principal agricultural credit systems of Europe are those of Germany and France. The German system is a mixture of cooperative and public, and that of France a mixture of private and public, about like our Federal Reserve System. Long term mortgage credit is provided in Germany by nine *Landschaft* banks, which sell debentures and make amortization loans running from thirty to seventy-five years. These are cooperative in that the members are unlimitedly liable for the loans; but are public to the extent of being granted special public prerogatives, such as the right to take possession of property without foreclosure. Intermediate credit for land development has been provided for by a system of public agricultural improvement banks, which, however, have not been widely used. Other forms of intermediate credit and short term credit are provided cooperatively by small local credit associations, known as *Raiffeisen* and *Schultze-Delitzsch* banks, both operating for the most part on the basis of unlimited liability. This is especially true of the

former. These public and cooperative agencies compete for business with an extensive system of strictly private farm mortgage companies and banks and commercial banks.

In France land credit is provided by the *Crédit Foncier*, modeled after the *Landschaft* banks but now maintaining the same relation to the public as the Bank of France, that is, a private institution with certain public privileges and responsibilities. Its loans are on amortization mortgages running from ten to seventy-five years, or on one to nine year mortgages without amortization. The *Crédit Agricole* is an adjunct of the *Crédit Foncier* which makes short term and intermediate loans. The cooperative credit institution in France is known as *Crédit Agricole Mutuel*.

AGRICULTURAL ECONOMICS.

UNITED STATES. As a separate branch of the social sciences in the United States agricultural economics has been in existence scarcely a quarter of a century. Agricultural colleges, authorized in the Land Grant Act of 1862, were actually established only after the Civil War, and legislation in 1887 provided for a system of experiment stations joined to the teaching institutions. The work of both these agencies, however, as well as that of the United States Department of Agriculture and state departments of agriculture, was organized primarily on a technological basis, and their field

of research and teaching was limited to the natural sciences as applied to agriculture. The federal government had, from the days when agricultural matters were handled by a section of the Patent Office, given some attention to commercial or economic problems as they arose, but it was not until 1922 that the Department of Agriculture formally organized a Bureau of Agricultural Economics. In like manner agricultural college faculties had from time to time made broad pronouncements on agrarian questions, but formulated their opinion concerning such issues on the basis of rather meager scientific investigation. The delimitation of agricultural economics as a special field of work in state institutions lagged behind even its tardy development in the United States Department of Agriculture.

Agricultural economics as a comprehensive treatment of the business phases of farming has developed from several more particularized interests, especially farm management, marketing, land policy and rural credits. In the early years of this century a small group of workers in the Office of Grass and Forage Plant Investigations of the Bureau of Plant Industry of the United States Department of Agriculture began to study actual practises on various farms with a view to determining why some farmers succeeded while others failed. In 1905 this work was recognized to the extent of being made the special task of a separate Office of Farm Management in the bureau. This office conducted numerous farm management studies emphasizing cost accounting, and in 1912 W. J. Spillman, in charge of the office, published a bulletin entitled "What is Farm Management?" (U. S. Department of Agriculture, Bureau of Plant Industry, *Bulletin no. 259*). This discussed in considerable detail the actual work of the office and also the general principles which it advocated for the successful organization and operation of the farm.

Meanwhile George F. Warren had been for some five years developing similar lines of activity at Cornell University. In 1911 the experiment station of that institution presented a detailed farm management survey of Tompkins County (Cornell Agricultural Experiment Station, *Bulletin no. 295*), which was the beginning of a large development of such work by experiment stations throughout the country. In 1913 Warren published a college text on *Farm Management* (New York), which was the pioneer work in the field and is still in wide use.

That conditions were ripe for development of this field was evidenced by the rapid spread of farm management courses in agronomy departments of most of the important agricultural colleges, generally followed by the setting up of a separate farm management department in the college and a farm management section in the affiliated experiment station.

The interest in problems of foreign markets, agricultural prices, marketing methods and reforms dates from the beginning of commercial agriculture in the United States. This interest received a sharp impetus from the "high cost of living" discussions which attracted such wide attention in the years immediately following 1909. An Office of Markets was established in the United States Department of Agriculture in May, 1913, to deal specifically with this group of problems. Meanwhile state departments or bureaus of marketing were being formed, classes in marketing were being organized in not a few of the larger agricultural colleges, and both research and teaching in this field were being expanded and to some degree systematized.

Somewhat broader than either of these special approaches was the movement begun at the University of Wisconsin about 1902 by Henry C. Taylor with the support and aid of Richard T. Ely. Although Taylor was primarily interested in the economics of production, he was less strictly commercial than the members of the farm management group. He was more concerned with problems of agrarian policy, particularly as related to land utilization and land tenure. The first book which included the term "agricultural economics" in its title was published by Taylor in 1905 (*An Introduction to the Study of Agricultural Economics*, New York). This volume had no sections dealing with marketing, rural finance, agricultural labor, wages, standard of living, costs of transportation, taxation or related problems that are so important in subsequent discussions of the farm problem.

At the same time that Taylor and Warren were establishing agricultural economics as a discipline in the agricultural college, Thomas Nixon Carver, approaching the same problem from the field of general economics, was conducting a regular class in agricultural economics at Harvard University, and in 1911 published a textbook of *Principles of Rural Economics* (Boston), followed five years later by a book of *Selected Readings*. Although the *Prin-*

ciples had a strongly classical flavor it supplemented previous writings by providing a "historical sketch of modern agriculture" and a systematic discussion of the "distribution of the agricultural income" as wages, rent, interest and profits. It contained also a chapter on problems of rural social life which discussed rural population, standards of living and group organization for the improvement of rural conditions.

Since the appearance of these three pioneer books, a voluminous literature has grown up. It includes several other general treatises and a host of specialized books on marketing, co-operation, credits, agricultural commerce, tariffs, economic history of agriculture, agricultural geography and the recent farm depression. A veritable flood of bulletins has come from the state experiment stations and the United States Department of Agriculture. *The Journal of Farm Economics* is in its eleventh volume (1929) and runs above five hundred pages annually. It is the official organ of the American Farm Economic Association, which has a membership of nearly nine hundred.

The discussion of theoretical aspects of the subject has lagged behind the flow of current and specialized material. This is a natural consequence of the practical character of much of the work in the field and the fact that the whole matter has been in rapid flux, with immediate problems monopolizing the attention of most of the workers. The situation is being remedied by the appearance of such volumes as John D. Black's *Introduction to Production Economics* (New York 1926) and Clarence L. Holmes' *Economics of Farm Organization and Management* (Boston 1928), which reflect the tendency toward broadening the theoretical foundations of the discipline. Equally strong is the tendency toward improvement of the statistical technique applied to the analysis of many of the problems presented.

The scope of research programs and the methods used in the several branches of the field have been reexamined recently by the Advisory Committee on Social and Economic Research in Agriculture of the Social Science Research Council. This committee, representative of all groups of workers and schools of thought, is responsible for a survey which provides a comprehensive and critical analysis of the entire range of methods of research and indicates quite clearly the trends of development. Further, more detailed investigations for

the separate branches of the discipline may be expected from the representative subcommittees of the advisory committee.

In the last decade the United States Department of Agriculture has considerably enlarged the scope of its work relating to economic aspects of agriculture. Particularly helpful was the consolidation of the Office of Farm Management and Farm Economics, the Bureau of Crop Estimates and the Bureau of Markets into a comprehensive Bureau of Agricultural Economics. This bureau, with its large staff of trained workers, carries on a comprehensive program in the gathering and analysis of data. It occupies a position of leadership among the state agricultural experiment stations, complementing their work and supplementing their resources where local funds and personnel are inadequate. Each state, however, is entirely free to develop an independent program dealing with local problems and meeting local needs. In general state as well as local interest and financial support have turned increasingly toward the study of the economic basis of agriculture in recent years, and the Purnell Act of 1925 makes available to each state experiment station an annual sum amounting to \$60,000 (in 1930 and thereafter), of which one of the chief specified uses is the expansion of research work in agricultural economics.

Meanwhile agricultural economics has been progressing rapidly as a teaching discipline. There has been an increase in residence and extension teaching in colleges and universities. The secondary schools also have turned their attention to this subject as a part of their programs of vocational agriculture; they have sought to develop both subject matter and methods which should meet the needs of those whose training will not go beyond the high school stage. Measures have been taken to assist the teaching and research personnel in securing advanced graduate training to a larger extent than has been possible hitherto. This is bound to produce not only an improvement in teaching but also a more thorough grounding of agricultural economics in general economic theory.

E. G. NOURSE

EUROPE. Agricultural economics in Europe is of considerably earlier origin than in America. For nearly a century *Agrarpolitik* (agriculture in relation to state and society) has been an established university course in Germany.

As early as 1851 Léonce de Lavergne, of the Institute of Agronomy at Versailles, gave a course in *économie rurale*. Emile Levasseur devoted to rural economics a part of his *Cours d'économie rurale, industrielle et commerciale*, first published in 1869. In some countries teaching still follows the outlines formulated by the early trail breakers. However, most of the present day college and university courses are a reflection of current research interests. Viewed in this light, agricultural economics is a development of only the last thirty years.

Since agricultural economics deals with practical problems, it is not surprising to find that the emphasis laid on the different branches of the discipline differs from country to country. In England "costings" have received the major portion of attention. In Denmark, Switzerland, Czechoslovakia and Sweden simpler farm accounts form the basis of agricultural economic research work. Norway is interested in the statistical measurement of the results of varying degrees of intensity of culture. Political events in central Europe have centered attention upon the land reform movement involving problems connected with the transformation of large estates into small properties. The agricultural economist of Italy has developed to a high degree the technique of farm land and farm income valuation. In France rural law and legislation are basic considerations. On the whole one is struck with the general absence of market and price studies so popular in the United States.

Of all European countries Germany, perhaps more than England, represents the fullest and most advanced development of agricultural economics. In addition to their interest in *Agrarpolitik* the Germans have devoted extended attention to farm management (*landwirtschaftliche Betriebslehre*), agricultural credit and co-operation, farm labor and the economics of land tenure and of land settlement. The students of farm labor are devising methods for increasing labor efficiency. In attempting to "taylorize" the farm the leaders of this new specialty (Seedorf at Göttingen, Falke at Leipzig and Derlitzki of the Farm Labor Experiment Station at Pommritz) have conducted researches dealing with the psychology of personnel management, analysis and standardization of tasks, relation between tool and task, environmental conditions of work and systems of payment. German economists pursue the study of the problems of land tenure and settlement with

unrivalled intensity. The foremost institution in this field is the Forschungsinstitut für Agrar- und Siedlungswesen, established by the government in 1921 and directed by Max Sering of the University of Berlin. Its numerous publications dealing with a variety of economic-agricultural subjects display a distinctly international viewpoint.

England, like Germany, has a well developed program of organized research in the general field of agricultural economics, notwithstanding what might be termed a too weighty dependence upon "costings." It is one of the few countries devoting organized research attention to the marketing of agricultural products. The Agricultural Economics Research Institute at Oxford under the direction of C. S. Orwin and the Ministry of Agriculture and Fisheries constitute coordinating centers. The institute has from its foundation in 1913 emphasized cost accounting as a method of research. The ministry also maintains an agricultural economic advisory officer at a number of colleges and universities for the purpose of conducting cost accounting studies. There is a definite realization that the restricted number of farms that can be handled by the "costings" method seriously limits the application of its results. During the last few years the tendency has been to experiment with other research tools, such as the collection of farm financial records and a wider use of the survey in order to furnish a broad base for generalizations, even though these will be less exact in details than "costings" figures.

Simpler methods of farm accounting for research purposes are used in Switzerland and Denmark. Ernst Laur, professor of rural economics at the Zurich Polytechnicum and director of the Union Suisse des Paysans, set the example for the extended use of accounting in obtaining farm organization data and research material on the economic status of a nation's agriculture. For the past thirty years the union has conducted each year a short course in farm accounting attended by a selected group of farmers from various sections of the country. Those who attend these courses agree to submit their accounts to the organization annually for analysis. As a result of this practise Switzerland has perhaps a larger volume of reliable data on the economic phases of her agricultural operations than any other country.

In Denmark the accounting methods are similar, but the records, instead of being kept by

the farm operators themselves, are compiled by paid consultants employed by cooperative book-keeping societies. Denmark had in 1927 about sixty agricultural bookkeeping organizations with over one hundred paid consultants. For research purposes the records of the local societies are analyzed by the semi-official central organization known as the Bureau of Farm Management and Agricultural Economics (Det Landøkonomiske og Driftsbureau) and directed by O. H. Larsen, professor of rural economy at the Royal Veterinary and Agricultural College in Copenhagen.

The Institute of Agricultural Accounting and Rural Economics at Prague (Zemědělského ústavu účetnickosprávočného Československé republiky), directed by Professor Vladimír Brdlik, also deserves mention. It published in 1926 an extensive four volume statistical analysis in several languages of the organization and output of agricultural production in Czechoslovakia.

Agricultural economics in Italy places an emphasis upon land valuation. This is due to the fact that the system of property taxes and of taxes on agricultural incomes, originally based on the principles of the "Milanese Census" of 1718, which measured and mapped each property as a basis for its valuation for tax purposes, has since developed into a complicated and intricate process of evaluating sources of farm incomes, calling for considerable training. In Italy the work of appraising land and farm incomes approaches a profession. The best examples of Italian scholarship in this field are Luigi Einaudi's "La terra e l'imposta" in *Annali di economia* (vol. i, 1924) and O. Bordiga's *Trattato di stime rurali* (2 vols., 1923-25).

No summary of the development and status of agricultural economics in Europe can fail to note the importance of unofficial agricultural associations as research and extension agencies. Throughout Europe these associations perform many of the educational, research and extension functions ordinarily handled by public agencies in the United States. Reference has already been made to the Union Suisse des Paysans. Boerenbond Belge and the Deutsche Landwirtschafts-Gesellschaft are also noteworthy examples of associations of this type. Perhaps the most influential farmer-controlled organizations from the standpoint of economic research and extension are the agricultural chambers as they exist in Germany, Austria

and Hungary. These chambers maintain experiment stations, conduct short courses and issue publications. Economic problems have a definite place among their numerous activities. The activities of the International Institute of Agriculture at Rome are also largely economic in nature. Three of its four major technical divisions deal with economic and social questions.

AGRICULTURAL EDUCATION. Education in agriculture is manifestly age old, arising slowly out of experience and the ancient philosophies concerning the nature of the world and the mysteries of plant and animal life. In its formal aspects, however, as a phase of technical or vocational education propagated by means of schools and societies, it is relatively a recent development. Modern science had its beginnings in the sixteenth and seventeenth centuries, and a long time elapsed before it came to be significant for agriculture. The University of Halle, founded in 1694, led the way in the introduction of new methods and subjects, including what were then beginning to take shape as the natural sciences. Locke, Rousseau, Pestalozzi and Philipp Emanuel von Fellenberg (1771-1844) were later noteworthy for their important contributions to education in natural science and to the development of schools of practical arts and manual labor, using farming and gardening as a basis. Much progress had been made in the teaching of the natural sciences by the end of the eighteenth century, and a number of important agricultural schools date from that time: in Bulgaria at Tirnova (1791); in Hungary at Zarvas (1779), Nagy-Micklos (1786) and Keszthely (1797); in Germany at Moeglin (1806), Tharandt in Saxony (1811) and shortly thereafter the agricultural college of the University of Leipsic and the agricultural college at Hohenheim (1818); in France at Grignon (1829).

The progress of science in relation to agriculture was especially stimulated by the researches in agricultural chemistry of Sir Humphry Davy (1778-1829) in London, Jean Baptiste Boussingault (1802-87) in Paris, Justus von Liebig (1803-73) at Giessen and Munich, and by the work in botany of Carolus Linnaeus (1707-78) at the University of Uppsala. During this same period, zoology, geology and mineralogy, important factors in the study of agriculture, also took shape as specialized fields of science.

While in a measure progress in agricultural education and experiment was a concomitant of progress in natural science, the fruitful application of the knowledge and methods of science to agriculture awaited more than a

century of development in the applied fields of natural science. But during the seventeenth and eighteenth centuries there developed in Europe a body of literature on agricultural subjects which played an important part in furthering the movement for agricultural education.

Throughout the nineteenth century the countries of central and western Europe matured and diversified their facilities for agricultural education and research. The maintenance of such facilities came to be regarded primarily as a function of government, although privately supported institutions and others fostered and maintained by voluntary farmers' societies, often with state subsidies, continued to develop. In general, elementary and secondary schools of agriculture profited most from the early impetus and soon became widespread. At present they differ greatly in organization and scope in the several countries, revealing adaptation to local requirements under the differing conditions as to literacy, agricultural resources, national wealth and public policy. These schools are predominantly the places where young persons are trained for farming, and they emphasize the acquirement of practical skills. As a result the colleges and university departments of agriculture have been freed for the higher aspects of education and research and they attract persons whose primary purposes are to prepare for scientific and professional posts and for the management of large properties. The close of the nineteenth century found these higher institutions in some of the central and western European countries on a sound scientific basis, the acknowledged leaders in the training of men, and models of organization.

Following the European War of 1914-18 there was a noteworthy expansion in every country of Europe. In respect of both lower and higher agricultural education and of facilities for experiment and research, the grants for new institutions and for the strengthening of existing institutions far surpassed in amount and significance the expenditures during any similar period in history. The acuteness of the food supply situation during the war and the urgency of subsequent economic rehabilitation unloosed new impulses and relatively large public funds for the substantial development of scientific agencies to aid farmers. While in other continents, with the exception of North America, there has not been comparable expansion, in every civilized country progress has been marked during the first quarter of the present century.

Facilities for experiment and research were developed during the nineteenth and early twentieth centuries both as parts of colleges and university departments of agriculture and as independent institutions. Throughout Great Britain and the continent the so-called agricultural experiment stations were, and are, typically independent institutions, each devoted to a single major field of agriculture, physically and administratively dissociated from the colleges and universities. There are a few exceptions. By reason of the existence of many independent experiment stations for the solution of problems of immediate practical utility, the scientists in the colleges and university agricultural departments and institutes have enjoyed greater freedom quietly to pursue knowledge in whatever direction their abilities and inclinations led them and to devote themselves to the broader, fundamental aspects of their fields.

With the exception of the British institutions, the college and university departments of agriculture in Europe have no responsibility for that modern educational device known as extension teaching. Such work, called agricultural propaganda in Europe, proceeds either directly from the ministries of agriculture or, more commonly, from farmers' societies, which frequently receive governmental subsidies for the purpose. Some form of propaganda service for agriculture now exists in nearly every European country, with the possible exception of Austria, Hungary, Rumania and Czechoslovakia, where this type of service is less clearly differentiated.

The progress of agricultural education and experiment in Europe supplied the pattern and the stimulus for its development in America. Of special influence in the early efforts in the United States was the work of the manual labor schools of Fellenberg at Hofwyl, Switzerland. Between 1819 and 1840 many schools of similar type were established in the United States, with agriculture and various mechanical arts as the center of interest. While many of these efforts were short lived, they laid the foundations for later successful institutions. Societies for the promotion of agriculture were the chief agencies in calling attention to the need for experimentation and demonstration in agriculture, for the selection and improvement of cattle, for the development of an agricultural literature and for the organization of courses and schools of instruction. Agricultural fairs, based on the successful English models, were

organized even in colonial times, and after 1807 these became important and permanent educational agencies, especially for the comparison and improvement of livestock. Agricultural periodicals, which began to appear at the close of the eighteenth century, served not only to set before the people useful information on a wide range of agricultural subjects but also to focus the attention of farmers and others on the desirability of establishing institutions in the United States for the teaching of science as well as the theory and practise of agriculture. Furthermore, prior to 1850, chairs of natural history, of agricultural chemistry and of agriculture as such found place in some of the colleges and universities of this country. These and other efforts combined to prepare for the great forward movement in agricultural education in the United States which came soon after the middle of the century. The first of the present system of agricultural colleges was chartered by act of the Michigan legislature on February 12, 1855.

The most significant legislation for agricultural education in the United States is the Morrill or Land Grant Act of July 2, 1862. It provided grants of public lands to the several states and territories, based on their representation in Congress. The proceeds from the sales of these lands were to be permanently invested and the income therefrom inviolably applied to the creation and maintenance of institutions, of which there was to be at least one in each state, and which were to give instruction in agriculture and the mechanic arts as well as in other scientific and classical subjects. These Land Grant colleges and universities were designed particularly to afford the industrial classes both a liberal and a practical education and subsequently have had a profound influence. Not only have they become the primary centers for higher education and research in agriculture and the mechanic arts, but many of them have risen to the first rank in the liberal arts and in the professions. Because of their sudden establishment in all of the states, their early years were full of difficulties. Qualified teachers in natural science were few, and there were practically no persons trained to teach agriculture. Agricultural textbooks were largely of foreign derivation, and there was very little tested knowledge based on American conditions. Little progress had yet been made in laboratory methods in science. Farming operations were crude, and in the agricultural depression which

followed the Civil War there was little incentive for students to take up a college study of agriculture. For thirty years the enrolments in agricultural courses were low, and farmers were skeptical. But progress was being made, teachers were being trained, facilities assembled, texts prepared, laboratory methods worked out, public confidence won, and in time the economic and the social as well as the scientific value of this vast educational undertaking was demonstrated.

Congress increased its financial aid to these colleges by the passage of the Second Morrill Act of 1890 and the Nelson Amendment to the Second Morrill Act in 1907. From the first, and in increasing extent, the state legislatures appropriated state funds to these institutions, and in most of the states such appropriations now constitute the chief source of support.

From the establishment of the Land Grant colleges and universities, the making of experiments and scientific investigations was considered an essential part of their work. It was apparent that if these institutions were to serve the country they could do so only through the development of a body of tested knowledge. By 1870 the organization of experimental work had begun. In 1875 the first of the formal agricultural experiment stations was established at Middletown, Connecticut (it was moved to New Haven in 1877), and in the following ten years such stations were established in sixteen additional states. These efforts led to federal legislation (Hatch Act, 1887; Adams Act, 1906; Purnell Act, 1925) for the establishment, and later the fuller development, of experiment stations in connection with all the Land Grant colleges and universities. The development of organized research marked the beginnings of vitality and public confidence in these institutions.

The long depression in farming came to an end about 1897. The new century opened with widespread general prosperity for agriculture, accompanied by its expansion and diversification. The first fifteen years of the twentieth century were marked by a rapid influx of students into the agricultural colleges. Many of the institutions underwent phenomenal growth in facilities and departments of instruction, and in specialization of teaching and research. Post-graduate study became a necessity for the prospective agricultural teachers and scientists, and a few strong graduate centers emerged.

A further expansion of facilities and fields of work, which followed the World War, is still actively in progress.

The agricultural colleges early sought to aid farmers in their immediate problems by means of addresses before agricultural associations, at fairs and on other occasions, and by contributions to the agricultural journals. About 1870 meetings called Farmers Institutes, at which members of the college staffs offered popular instruction in agriculture, were held first in Kansas and Massachusetts, then in other states. The movement for organized extension teaching from the colleges got under way about 1892 and gradually became a recognized function. It was expanded to include itinerant lecturers, local short courses, movable schools, correspondence and reading courses, publication of bulletins on practical and scientific matters of interest to farmers, field experiments and demonstrations, and fair exhibits. As the demand for this work grew, a movement developed to obtain federal aid for the extension services. These efforts culminated in the passage by Congress of the Smith-Lever Act (1914). Under the stimulus of this act, which required practically equal funds to be provided by the several states, the benefits of the agricultural colleges and experiment stations have been brought to the farms and rural homes throughout the nation, with marked results in improving agricultural practise on the technological and business sides and in the elevation of country life. The extension service field force is by now a highly developed and efficient organization. It comprises specialists in the several major branches of agriculture and resident agents in the counties, known as county agricultural agents, home demonstration agents or boys' and girls' club agents.

Before the passage of the Morrill Act of 1862, the lower, practical schools of agriculture had largely disappeared. For a time the agricultural colleges offered a considerable amount of instruction of secondary grade in order to attract farm boys. The close of the nineteenth century saw the beginnings of a new movement to encourage the teaching of nature study, elementary agriculture and school gardening in the elementary schools. By 1915 the teaching of agriculture in public rural elementary schools was required in twenty-two states, and was actually offered in some schools in practically all of the states. This work is still in process of development and adaptation to the educational

and prevocational needs of country children.

As the colleges matured and raised their standards they gradually discontinued their instruction of secondary grade or relegated it to brief winter courses. Furthermore it became evident in America, as it had long been evident in Europe, that only a relatively small proportion of farm children would find it practicable to attend the agricultural colleges, and that the latter were destined to become primarily centers for the training of leaders—teachers, investigators and experts—and that provision for secondary instruction should be made independently, either in special agricultural schools or in the established high schools. Between 1880 and 1915 a number of special schools of agriculture were opened which flourished for a time. Out of a wide variety of experience and educational experiment finally emerged the nation wide system of public high school vocational departments of agriculture. The most rapid development of such departments followed the passage by Congress of the Smith-Hughes Vocational Education Act in 1917, under which large grants of federal funds came to the states for the establishment and maintenance of vocational agricultural education as a permanent part of the public high school system of the United States, and for the training of teachers for these vocational departments. Within the following five years every state had both provided facilities for the training of teachers and instituted courses of one to four years in length in a great many of the rural and village high schools.

The American structure for elementary and advanced agricultural education is now complete in its main outlines. The future will be concerned with a better adaptation of these institutions to their function in the educational system, with improvement in the professional preparation of teachers and in the methods of instruction, and with the discovery and formulation of a scientifically sounder body of knowledge for utilization at the several levels of instruction.

AGRICULTURAL EXPERIMENT STATIONS are institutions for research in agriculture, each with a trained personnel headed by a director or other administrator, provided with reasonably permanent financial support, and equipped with buildings, experimental fields, livestock, laboratories and other necessary equipment. Discoveries in the natural sciences promoted agricultural research by stimulating inquiry into the relation of science to agriculture. Research stations were preceded by individual experimentation, especially of wealthy and public spirited "country gentlemen," but the superiority of properly constituted institutions over individual effort soon became apparent. Notwithstanding a growing recognition of the public importance of agricultural research, experiment stations, especially in Europe, for many years received their principal or entire support from private sources.

The Rothamsted station, established in 1837, is the most noted of the great centers of agricultural research in Great Britain. The Royal Agricultural Society, established in 1838, "proclaimed the alliance between practical farmers and men both of capital and of science," and became a potent factor in promoting scientific

agriculture. Recent outstanding developments in British agricultural research are the increase in its support by the imperial government and the extension and coordination of research throughout the empire. The Development Fund, instituted in 1909 and augmented in 1921, is the chief source of government subsidy, and additional aid is granted through the Empire Marketing Board appointed in 1926 on the recommendation of the Imperial Economic Conference in recognition of a unity of interest in the progress of agriculture.

The Australian Council for Scientific and Industrial Research, created in 1925, provides for cooperation in agricultural research in the state departments of agriculture and in the universities. In New Zealand research is conducted on experiment farms, in the colleges and universities, and in the privately endowed Cawthron Institute. The Veterinary Research Station at Onderstepoort, South Africa, conducts a broad program of investigation. Guelph College, now affiliated with the University of Toronto, was for several years the only Canadian agricultural experiment station. The first plan for coordinated effort in Canada, formulated in 1884, was called the Dominion Experimental Farm System and consisted of a central station near Ottawa and branches in the various provinces. Agricultural research in India is conducted mainly in the provincial departments of agriculture organized in 1906 and in the Imperial Agricultural Research Station at Pusa. Research in tropical and subtropical agriculture is receiving increased attention in India and in the colonies and dependencies. The Imperial College of Agriculture at Trinidad was opened in 1922, and the Amain Institute in Tanganyika, East Africa, organized by the Germans, is being restored. These institutions are parts of a plan, evolved at the First Imperial Agricultural Research Conference held in London in 1927, for a chain of tropical and subtropical experiment stations.

In continental Europe also, recent public policy in agricultural research is marked by expansion, coordination, centralization and increased support. Much of the early stimulus to agricultural research came from Germany through von Liebig and other scientists and through experiment stations, the first of which was founded in 1852. Experiment stations have been established for a long time in France and were reorganized in 1921 into a more centralized system under the Institute of Agricultural

Research subordinate to the Ministry of Agriculture. In fact the growth of experiment stations as agencies for agricultural improvement is universal.

Agricultural experimentation in America, as in Europe, was begun by individual effort and stimulated by agricultural societies and men of public spirit. President Washington, in 1796, recommended to Congress the establishment of a National Board of Agriculture. The New York Agricultural Society founded a chemical laboratory in 1849; and in 1856 the Maryland legislature established an agricultural college and provided for experimentation on the college farm. Research, including field experiments in many phases of agriculture, early became part of the regular work of the Federal Department of Agriculture, established in 1862.

The Land Grant Colleges, founded by the Morrill Act of 1862, experienced a growing need for reliable information, for residence teaching and for more helpful contact with farmers. Accordingly the establishment of agricultural experiment stations was recommended at a convention of representatives of these colleges called by the United States Commissioner of Agriculture in 1872. Before Congressional action was secured, several states established stations—Connecticut and California in 1875, North Carolina in 1877, New York in 1879 and New Jersey in 1880. By 1886 the Committee on Agriculture of the House of Representatives, reporting favorably the Hatch Bill, said that experiment stations had been organized in many state colleges and that "a very large number of the colleges established under the Act of 1862 are doing important work of precisely similar kind." The bill, adopted in 1887, granted \$15,000 to each state and territory for support of experiment stations "to conduct original researches or verify experiments . . . bearing directly on the agricultural industry of the United States . . . having due regard to the varying conditions and needs of the respective states and territories."

The national system of state experiment stations operates under the coordinating influence of the Office of Experiment Stations of the Federal Department of Agriculture, which also administers the nationally financed stations in Alaska, Guam, Hawaii, Porto Rico and Virgin Islands; serves as a clearing house of agricultural information for the United States and foreign countries; and issues publications reporting the status, progress and needs of

research. The principal publication, *Experiment Station Record*, has been published since 1889.

The Adams Act, passed by Congress in 1906, provided an additional \$15,000 for station work in each state. The Purnell Act of 1925 broadened the field of research to include agricultural economics, home economics and rural sociology, and further increased the federal support so that in 1929-30 the federal appropriations for the experiment stations in each state aggregated \$90,000. Federal support and cooperation have afforded a guiding influence in agricultural research, without curtailing the necessary freedom for independent endeavor. It is indicative of state and local interest that revenues of the experiment stations have increased more rapidly from sources within the states, such as state appropriations, station revenues from the sale of products, fees, contributions by individuals and local communities, etc., than from federal appropriations.

Testimony to the value of experiment stations is found in the rapid increase in public funds for their support in many countries, despite the demand for retrenchment in public expenditures since the World War. That conflict, and the agricultural depression which followed it, emphasized the dependence of agriculture on technological and economic information. A more fundamental cause of the advancement of agricultural research may be found in a growing faith of the masses in the power of science to solve their problems, and in the well founded belief that this research benefits not only the rural but quite as much the rapidly growing urban population to whom improvement in agriculture offers the best assurance of an adequate supply of food in the face of a diminishing supply of virgin agricultural land.

AGRICULTURAL FAIRS. The agricultural fair is a rural institution which is found in virtually all countries of the western world. It is not a market but an exhibition having for its chief aims the improvement of agriculture and the provision of a wholesome form of amusement for the rural people. In the United States and Canada it is known as the agricultural fair, while in Europe, Australia and in some other portions of the New World, it is known as the agricultural show.

The history of the agricultural show in England dates back to the last quarter of the eighteenth century, when agricultural clubs and societies were first organized. These clubs had for their object the improvement of agriculture, and the show was one of the chief means of achieving this end. The establishment of these clubs and the holding of shows were only a part of a larger agricultural awakening which was under way at the same time that the industrial revolution was in progress. The making of hay through the use of clover and other improved grasses came to be common at this time, and scientific breeding resulted in the development of much larger and better sheep and cattle. Arthur Young and gentlemen farmers wrote on agricultural subjects and added zest to the organization movement which culminated in the establishment of the Board of Agriculture in 1793. Among the earliest agricultural shows in England were the Lancashire Society Show held in 1761, and the Bath and West of England Show held in 1777. These were followed by many other local shows and plowing matches. The first national show was held by the Board of Agriculture in 1821.

The practise of holding local and national shows in England has continued to the present time and is also in vogue on the continent. Some of the more important shows in other European countries, are: the Concours Général Agricole de Paris, the East Prussian Agricultural Exhibition, the National Show organized by the General Association of Breeders in

Spain, and the International Exhibition of the Cheese Industry and Trade of Italy.

The history of the development of the agricultural fair in the United States is similar to that of England, but the movement came about a quarter of a century later and was not well under way until 1819. Agricultural clubs and societies were organized as early as 1785, and suggestions were made that these societies organize fairs and offer premiums for the best exhibits.

Considerable interest in agricultural organization centered in Washington, D. C., and it was there that the first fairs in the United States were held. A series of three fairs was begun in 1804. These probably grew out of a suggestion made by the first United States Commissioner of Patents that market days be established for the sale of cattle and local products. The exhibit, however, must have been the chief feature of these events, inasmuch as the city government and private citizens contributed funds for the payment of premiums. After a lapse of a few years the Columbian Agricultural Society began in 1810 to hold a series of five fairs at which sales were also featured. Auction facilities were provided at the close of the fair for the sale of cattle and various articles. This procedure, it was thought, contributed to the success of the fair.

The fact that these Washington fairs combined exhibits with markets might furnish a basis for the inference that the agricultural fair sprang from the old mediaeval fair or market. History, however, seems to show that this is not the case. In England the agricultural fair was conceived and first fostered by agricultural clubs, and in America it was likewise first suggested by clubs. The real beginning of fairs in the United States is found in the activities of the Berkshire Agricultural Society organized under the leadership of Elkanah Watson at Pittsfield, Massachusetts, in 1810. This society became the first permanent fair association in America. In 1819 the legislature of the state of New York appropriated \$20,000 for two years to be divided among its county fairs. After a few years the states generally adopted the policy of subsidizing fairs.

The period running from 1850 to 1870 has been designated too absolutely as the "golden age of the agricultural fair" in the United States. Since the seventies the institution has experienced a phenomenal growth in the number and kinds of fairs held, in the attendance,

in the value of premiums offered and in the value of buildings and grounds owned by fair associations. Rubinow states that "fairs and expositions have multiplied so rapidly that it is not feasible to try to chronicle the actual number in the United States. More than 3,000 fairs, including state, district, county, community, township, school and street types, are held every year at various seasons." E. L. Richardson, President of the International Association of Fairs and Expositions, which embraces in its membership fair associations of the United States and Canada, states that 39,468,550 people were in attendance at all fairs held in the two countries in 1927. The average value of buildings and grounds of members of the International Association is placed at \$1,078,539.

State and county fairs are generally conducted by corporations known as fair associations or agricultural societies. They are usually incorporated and as a rule receive state aid. Inasmuch as cooperation is an important aspect of a fair, it has been urged that voting be restricted to one vote per member, irrespective of the number of shares held. The community fair is usually fostered and managed by some rural organization. Where no organization of any kind exists, merely a loose association is effected for the purpose. The conduct of the state and county fairs is made amenable to the state authorities through the auditing of books of record and through the inspection of exhibitions by duly authorized agents. State fairs usually employ a permanent secretary, while county associations can get along with one serving only part of the year. This officer, who may also be the treasurer, is the life and spirit of the organization. He must know agricultural life and be familiar with social organization. He is usually assisted by a number of committees as follows: premium, finance, program, grounds, reception, school, entertainment, contest, young people's exhibits, concessions, entries and exhibits, and memberships. The most successful fairs cooperate with all public and private agricultural organizations. The support of the state department of agriculture, the college of agriculture, the experiment station, and the extension service with all its local organization, as well as cooperative societies and all private agricultural societies, is solicited by the successful fair secretary. Team work or cooperation is in fact the essence of success in fairs. The exhibits having the greatest educational value are frequently those which are prepared by depart-

ments of agriculture and colleges of agriculture.

The financing of the fair is often a problem. State appropriations, gate receipts and private subscriptions are sometimes insufficient to meet all expenses. Concessions for amusements are therefore generally regarded as necessary, and these concessions, it is complained, are not always of a desirable sort. To be eligible for state funds for maintenance, fair associations in Ohio must bar games of chance, doll racks and other similar concessions, and it has been demonstrated that successful fairs can be conducted without them. Horse racing is often a popular feature in the United States, and pony races and horse jumping are organized in England.

The chief functions of the agricultural fair are the education of the public and the furnishing of wholesome amusement. Exhibits and demonstrations can be presented so as to attract the crowd and drive home important principles of applied agriculture. Demonstrations are concerned not only with the production of better crops and livestock but with the preparation of these goods for the market. Lectures on various agricultural topics are desirable if they are of a popular kind. The crowd is in a playful mood and is looking for entertainment as well as instruction. The occasion of the agricultural fair is in fact a show day, a gala day, and a time when a friendly spirit of rivalry prevails.

AGRICULTURAL HOLDINGS ACTS. *See* ALLOTMENTS; SMALL HOLDINGS.

AGRICULTURAL INSURANCE. The term, as commonly used, embraces all forms of insurance needed by farmers or agriculturists. In a narrower sense it refers particularly to such forms as crop and livestock insurance, which apply largely or exclusively to farm risks.

Hail insurance on growing crops, the only form of crop insurance generally available, is said to have originated in Germany in the latter part of the eighteenth century. It was introduced into the United States about 1880, and since 1910 has been written in considerable volume. During the season of 1919, which marked at least a temporary high point in such insurance, the hail premiums on American crops amounted to approximately \$30,000,000, and the insurance in force exceeded half a billion dollars.

In the United States, as well as in several other countries, hail insurance is written by three groups or classes of insurance agencies: first, joint-stock insurance companies which write various kinds of property insurance; second, mutual hail insurance companies; and third, state hail insurance funds or departments, which in this country are limited to North Dakota, South Dakota, Montana and Nebraska. In volume of hail insurance written, the joint-stock companies are approximately as important as the other two groups combined. The cost of hail insurance in the United States varies with different crops and localities and also with the agency employed, the rates ranging from about \$2.00 to \$15.00 per \$100 for the season, with a weighted average cost of about \$5.00 per hundred.

Insurance of crops against damage by frost has also been written in parts of Europe and elsewhere. In the United States such insurance has been limited largely to sugar cane in Louisiana and to citrus fruit in Florida and California.

Attempts to write so-called all-risk crop insurance for individual farmers, covering against substantially all important hazards beyond the control of the farmer, including losses due to price fluctuations, have hitherto proved discouraging. Since 1920, when a second major attempt to develop such insurance resulted in heavy losses, due in this case to a well-nigh unprecedented drop in agricultural prices, such insurance has been limited largely to protection covering loans or advances made to organized groups of fruit and truck growers in selected areas. All-risk crop insurance, covering at least a substantial part of the annual investment in crops, represents a real need on the

part of farmers. Particularly is this true in cases where considerable diversification is impracticable.

In many of the European countries a very large percentage of all horses, cattle and other livestock is insured. This insurance is carried mainly in mutual companies, although a number of joint-stock companies also are found in this field. The numerous local livestock insurance societies are usually in part reinsured in larger regional societies, and not infrequently they are subsidized by the state governments. Mutual livestock insurance in some form is said to have existed in Europe for seven hundred years or more.

In the United States most livestock insurance companies that have been organized either on the mutual or on the joint-stock plan have rapidly disappeared for lack of patronage. The few and relatively small mutual livestock companies, about twenty-five in number, that have survived for any considerable number of years are limited almost entirely to Pennsylvania and Ohio. Most of the livestock insurance in the United States carried on the joint-stock plan is now on the books of one relatively small company, although during the recent high price period which came to an end in 1920 there were nearly a score of such companies in operation.

That livestock insurance has remained so unimportant in the United States, as compared to its development in many of the older countries, is no doubt in part explained by the absence of numerous small farmers to whom the loss of a single animal is a serious disaster. To some extent the situation may be the result of an inclination on the part of American farmers to carry unduly heavy risks individually, rather than to pay the necessary cost of protection on a commercial basis or to cooperate with other farmers in a mutual livestock insurance company. In this form of insurance, even more than in others, successful operation on a mutual basis requires close supervision for the avoidance of needless losses and unjustifiable claims.

American farmers quite generally carry fire and windstorm insurance on their property. Most of the joint-stock fire insurance companies, as well as the larger general mutuals, insure some farm property against these hazards. In this field of insurance, however, American farmers, as well as those in Europe and elsewhere, have succeeded well in their mutual enterprises. There are nearly two thousand farmers' mutual fire insurance companies in the United States, with

a total membership of about 3,240,000 and total risks approximating ten billion dollars. This insurance is carried at an average annual cost of about twenty-six cents per hundred dollars, which is very materially below the average of commercial rates. About 13 percent of these farmers' mutual fire insurance companies write also insurance against windstorm.

There are, in addition, about sixty specialized mutual windstorm insurance companies in the United States that insure farm property either largely or exclusively. These companies carry total risks amounting to about two billion dollars. The cost of windstorm insurance on farm property varies for different parts of the country from about one fourth to one half the cost of fire insurance.

A number of mutual companies have recently been organized to insure American farmers against the hazards involved in the ownership and operation of automobiles. The largest of these mutuals now operates in a score of states, while another operates in four states. The others are more local in their operations. These mutuals have hitherto given protection at a substantial saving to their members as against the cost of automobile insurance on a commercial basis.

AGRICULTURAL LABOR. Since the pursuit of agriculture has from time immemorial made the greatest demands upon the activities of the

human race, both the type and conditions of the employment it gives rise to are economically and socially of extreme importance. Even nowadays four fifths of the demand for manufactured products emanates from tillers of the soil, and the bulk of the world's population is engaged in the manual processes of food raising. Among early civilizations slave labor played an important part and represented the main alternative to a system of occupation by small owners in times when hired labor was scarce. It was employed in Egypt, in Persia and in Babylon, and the Romans made such progressive use of slaves that during the later periods of the republic most rural workers were slaves, laboring under overseers, often for absentee masters. Designated as *soluti* (when free from personal restraint) or as *vincti* (when worked in fetters), these *servi* numbered within their ranks both general laborers and specialists. Records are available as to the cost of their maintenance, the nature of their dietary, and the numbers necessary to cultivate different types and areas of land; calculations based on this material show that, while the expense of maintaining a Roman slave must have been equivalent to the wage paid to a hired European worker of the late eighteenth century, his effective output fell below that of the latter. Pliny and other contemporary writers, indeed, commented upon the uneconomic nature of slave labor. Among the Greeks, although agriculture was generally regarded as the most honorable of all professions, it was nevertheless considered to be a suitable employment for slaves, who ultimately outnumbered other types of workers. In western Europe where the transition from village community to manor presents difficult problems in connection with the status of individuals, slavery existed until after the Norman conquest of England. Thus *Domesday Book* records 35,000 "freemen," and 25,000 slaves, as compared with 200,000 villeins and cottars who, if physically free, were economically attached to the soil. Thereafter slave labor, as opposed to peonage, was confined to the southern states and the West Indies, where its history is common knowledge.

Throughout Europe serfdom, as represented by the manor, was predominant for centuries, the various classes of tenants holding their arable strips and enjoying other rights in return for services (e.g. boon-work and week-work) rendered to the lord. This system, which called for the cooperative use of implements and

numerous combined acts of husbandry, was ill adapted to survive the introduction of a monetary system or the growth of population, so that even in the thirteenth century weekly wage earners began to appear. This factor, combined with the gradual substitution of money rents for personal services, permitted tenants to devote themselves to the cultivation of their own holdings. So important a movement, occupying centuries in development and assuming various shapes in different countries, was expedited by the onslaught of the Black Death, which placed those who survived it in a position to secure greater personal independence at the expense of less equality of status, and initiated competition in wages and in rents. Thereafter, while the executive rigorously suppressed uprisings, the English landowners adopted sheep farming as a means of reducing their labor expenditure. Despite the survival of a considerable amount of villein-tenure in the shape of copy-hold, the ownership of land fell progressively into the hands of those who by trade and commerce had secured the means to acquire it. Enclosure, whether for the extension of grassland farming in the fifteenth and sixteenth centuries, or as part of the reverse process entailed in the increased production of wheat at the end of the nineteenth, inflicted hardship on the lowest ranks of the agricultural community, for at each period tens of thousands of peasant occupiers and owners were either deprived of their holdings or otherwise unfavorably affected. Too much credence, however, must not be given to exaggerated statements that the "yeomanry" was, upon either occasion, wiped out. After the Napoleonic wars the condition of the English agricultural laborer, who in the meantime had participated in the changing fortunes of his industry, definitely deteriorated. Faced by unemployment and by the hardships attendant upon the prevailing system of poor-relief, he once more attempted to exercise force, upon occasion destroying the newly invented machinery which he believed to be responsible for his economic disabilities, just as his forbears had treated manorial records. The industrial revolution simultaneously deprived his wife and family of earnings gained in cottage industry. The Poor Law system, which had alternated between excessive severity and the indiscriminate charity associated with "Gilbert's Act" and "Speenhamland," was drastically altered to meet the new conditions.

Subsequently "outdoor relief" was generally refused to the able bodied, the burden of local taxation (a disproportionate amount of which fell upon rural areas) was lightened, and farmers were enabled to meet with more confidence the demand for an augmented home supply of foodstuffs. The hereditarily landless laborer, despite such electoral concessions as the Reform Acts, was definitely confirmed in the situation toward which he had drifted after the fifteenth century. The period of high farming that followed saw him, despite the repeal of the Corn Laws, numerically at his greatest strength and enjoying an alleged "Golden Age." His social circumstances were still, however, untouched.

In other European countries serfdom survived the Middle Ages, being ultimately abolished by revolution, as in eighteenth century France, or by more constitutional means, as in nineteenth century Germany, in most cases peasant proprietary taking its place. In Russia, prior to the Great War, despite measures to establish them as tenants, those peasants who were not cultivating the open fields on mediæval lines were laboring on the estates of great landowners under conditions akin to servitude. While the universal post-war demand for freer access to the soil by those cultivating it resulted in the expropriation of millions of acres and their reallocation in small units, practical experience was unfortunately not always regarded as an essential qualification on the part of claimants; thus the urban populace too often secured preferential treatment and the transference did not afford a convincing demonstration of the value of widespread peasant ownership. Within a few years, however, modifications were effected in the land legislation of many European states, with the result that private ownership was in certain circumstances recognized in Soviet Russia, and elsewhere the area that an individual might hold was increased. In England, while the total of statutory small holdings (i.e. those below fifty acres) tended to remain stationary, the number specially created exceeded 20,000, provided at a very heavy cost. Here the main qualification was not experience but military service.

In the United States of America the early colonists introduced the systems of tenure and of cultivation with which they were familiar; but scarcity of labor, together with abundance of land, invariably raised difficulties, and to meet them, combined or forced labor were the

only alternatives. Two hundred years later, when railway construction and other works of development had withdrawn men by the hundred thousands from agriculture, the widespread adoption of machinery saved the situation in the face of rising costs and falling prices. In the southern states, notably Alabama and Georgia, peonage, either of criminals or colored labor, flourished until rendered progressively ineffective by legislative action.

In France, Denmark and such areas as are comprised in the southern and western portions of Germany the problem of the agricultural laborer assumes a different aspect, for peasant farmers utilize immigrant or seasonal helpers from neighboring states to work under conditions often the reverse of satisfactory. Small farm units, therefore, not only make excessive demands upon the time and strength of their owner and his family but may also give rise to extraneous abuses. On the other hand, in the United States and in Canada, the difficulties of assimilating a permanent influx of all the races of Europe and Asia has had to be faced, their divergent values as citizens and workers adding complications, of which not the least has been the tendency to form national group settlements.

In so far as the proportion of hired workers to farmers is concerned, the British Isles provide an extreme case, for employees outnumber employers by more than two to one. On the other hand in the United States less than half the total agricultural population is of the wage earning type. In most countries there has emerged, at some time or other, a system of voluntary "gang-labor." In the arable districts of England in the middle of the nineteenth century many thousands of persons, mainly women and children, were so employed under conditions which soon called for active intervention. In California Japanese, in Texas Mexican, workers have thus been utilized on a large scale. Such cases must be distinguished from the universal employment at certain seasons of extra hands which makes the enumeration and definition of agricultural workers so difficult and frequently gives a fallacious appearance to official statistics. Part time employment varies with the type of farming pursued, and in many instances (e.g. the presence of sugar beet or the proximity of forests) the establishment of grouped small holdings is facilitated by the opportunities thus afforded for winter, or off season work. Actual copart-

nership in agriculture has seldom met with success, for the relatively low profits—with a possibility of none—to be divided, combined with the slow turnover of capital, have formed an insufficient incentive to extra toil.

The agricultural worker, master perhaps of a dozen tasks, none of them simple and all calling for broad judgment as compared to that demanded of the urban machine minder, has earnings low in comparison with those of the industrialist, but not so meager as a casual inspection of cash payments alone would indicate. Thus the total emoluments of the rural employee may include such payments in kind as the provision of food and fuel; free occupation of plots of land; use of teams; additional money for specific work (e.g. harvest); piece work earnings; provision of a dwelling free or at an uneconomic rent; overtime remuneration. There must be added the earnings of wife and children, the labor of the latter being often regarded by employers as particularly valuable in keeping their land clean. Such are the factors which, in combination with the freer and healthier life of the countryside, generally maintain a sufficient supply of labor. That unemployment in agriculture is not a common feature is evidenced by the widespread disinclination to insure against it by both employers and employed.

The use of machinery, which in parts of the world has made possible the cultivation of as much as a square mile by one man, has naturally tended to reduce the number of workers; but in the Old World, where physical and economic conditions are peculiar, the manual work performed by cheap labor is displaced slowly. Thus in the arable districts of England it is usual to find four persons employed per hundred acres; while the grassland farmer utilizes about half that number of slightly better paid hands. The effect of the size of the holding on labor density is striking, for on English farms of from one to five acres the total number of workers (including members of the occupant's family) is 13.4 per hundred acres; on five to fifty acres it falls to 6.5; on fifty to three hundred acres to 3.3; and on over three hundred acres to 2.6. The higher proportions are of course universally found in suburban market gardening and fruit growing districts. In densely populated Holland and Belgium, as also among the teeming Chinese, where land is relatively scarce and therefore dear, the maximum output is desirable; in the western world this is

secured by peasant proprietorship, and in the East is secured also by the cheapness and abundance of human labor. In both cases a high return is secured from the soil, and output per acre is the criterion of successful farming. In the New World the greatest output per person employed is aimed at on land which is abundant and cheap. Thus it happens that the bulk of the foodstuffs imported into Europe in competition with the high-yielding soils of that continent comes from land giving perhaps half the returns obtained there; for although the laborer in the United States, Canada and Australia may be paid twice what he would earn in Europe, the cost of his labor per unit of produce is relatively small, so great is the economy of large single-producing units. It is, indeed, generally found that, as the size of holding increases, the value of the output per person employed moves upward. In English arable farming the proportion of the total expenditure attributable to labor ranges from 20 percent up to nearly 50 percent, averaging some 30 percent. The most promising remedy against increasing labor costs would appear to be an extended use of mechanical aids and a close study of the psychology of the worker. In the latter connection it can be shown that reduction in hours of labor within limits does not adversely affect output.

The agrarian policy, so widely pursued during the decade after the war, inevitably touched the hired land-worker, whose economic position was thereby improved. In England the provision of wages boards was effective in raising cash wages by some 20 percent, and in real wages the English worker is, together with the Dane, the highest paid agriculturist in Europe. Although it is difficult to compare conditions on the western side of the Atlantic, it may be pointed out that wage payments have in general conformed to fluctuations in the cost of living and that nothing but the depression through which agriculture passed prevented the rural worker from securing those higher real wages that fell to the general laborer. In 1926 American farm wages averaged 71 percent above the pre-war parity as against a cost-of-living increase of 72; industrial wages ranged from 100 to 150. In England, with a cost-of-living index augmented by 66 to 68 percent, agricultural wages in 1926 stood at 76 percent, and those of general laborers about 100 percent, above the normal.

In one respect the agricultural worker falls behind his industrial brother, for the trade

union movement, starting in England in the first half of the nineteenth century and taken up largely by the industrial trades of that and other countries, is still mainly confined to the industrial trades. Despite the work of enthusiastic philanthropists and political organizers, the rural worker remained aloof. In England, for example, rarely more than a tithe of the possible membership has at any time been secured, the actual numbers fluctuating with political and social conditions. The reasons are obvious: an industry composed of scattered and often inaccessible units; the close personal relationship engendered between master and man; the small financial resources of the workers, to whom a subscription of even a few cents a week implies sacrifice; the conservative habits of mind of those associated with the land; the futility of the strike as a lever in face of the slow processes of nature and the abundance of alternative forms of labor. Thus every attempt at direct action in agriculture has been foredoomed to failure, and those responsible for the direction of union policy have wisely devoted their energies to campaigns for social betterment.

In almost every country of the world the amenities of the rural worker's life have steadily increased. Since the middle of the nineteenth century, housing, education, the hours and conditions of labor, and emigration have received growing attention, and accordingly the disparity between the standards of the town and those of the country is being reduced. Work has been made more congenial and its hours curtailed. The growth of invention, represented by the automobile, the wireless, the telephone and the bicycle, enables the countryman to participate in the advantages of urban life, and may check the widespread movement townwards, which everywhere, from the mid-nineteenth century on, has been a familiar feature. It may be claimed that in civilized countries the hired land worker enjoys as good an expectation of life as does his town cousin; indeed his better physique secures his preferential selection in such callings as the army and the police force. He is often housed as well as his employer. There are few states which do not encourage, by means of special schools, technical colleges or provision for scholarships, his education and that of his family. In most countries, again, his feet are set upon the first or second rungs of the agricultural ladder, since he is generally accorded

preference when seeking a state-provided holding. Once so established, special provision is always made for supplying him with credit, machinery and an outlet for his produce; in certain cases group settlements give the practical training which he may need. Further ascent of the ladder is then a matter for himself alone. Workers in all countries and in all ages have climbed to the top; but it must not be forgotten that success in agriculture, as in other walks of life, depends upon ability, character and determination, not merely upon technical skill fostered from outside sources.

AGRICULTURAL MACHINERY. Implements operated by animal power have been employed in agriculture since prehistoric times. Oxen and horses were used in plowing, harrowing and in turning revolving pumps and mills. In the eighteenth century important improvements were made in the implements used in cultivation. This period witnessed the introduction of Jethro Tull's horse drill, horse hoes, horse rakes, Meikle's threshing machine, Eli Whitney's cotton gin, crude machinery for crushing sugar

cane, and plants for boiling sugar and preparing indigo. Yet the general application of mechanical contrivances in tilling the soil, planting seed and garnering the crop did not come until the second quarter of the nineteenth century.

Since then the steel plow has come into general use not only in the new countries, where lack of man power placed a premium on superior implements, but also in older, more settled agriculture. Numerous adaptations have been made for special purposes such as hillside plowing and the plowing of different varieties of soils. Sulky plows, disc plows and two-bottom (gang) plows pulled by four to six horses have been widely adopted. Plows with many bottoms have been developed for use with tractors. Much progress has been made in the development of various types of harrows, pulverizers, land packers, combinations of the harrow with seeders and planters, and two to four-row cultivators. Sowing and planting have been facilitated by the invention of grain drills, automatic corn planters, cotton and potato planters and special machinery for spreading fertilizers.

During the first three decades of the nineteenth century there were many attempts to invent a horse drawn reaper, but no practicable implement was achieved until the appearance of Hussey's and McCormick's reapers. By easy steps the reaper was perfected through the addition of a self-rake, a platform for the binders and finally an automatic binder using at first wire and then twine. An adaptation of the grain binder is the corn binder, and machines for harvesting soy beans, sweet clover and grain sorghums. Flax harvesting has been facilitated by the recent invention of the flax puller. Cotton picking machines appear to be the next addition to the series of mechanical harvesters.

Threshing machines run by horse power, steam or gasoline have gradually replaced the flail and hand winnowing devices. Threshing machines have also been developed for grass seed, soy beans and peas. A most important recent development is the grain combine, which unites the processes of harvesting and threshing. At first this machine could be used only in fields where the grain ripened uniformly, as in the semi-arid dry farming areas. In recent years it has come to be fairly common to cut the grain and throw it into windrows for drying, the combine following later, picking up the windrows and threshing out the grain. A combine adapted to corn harvesting, husking and shelling is said to be in process of development.

The old laborious processes of hay making have largely been eliminated by mowers, horse rakes, tedders, stackers and loaders; and hay drying equipment has been invented to reduce risks of loss from rain. Handling and utilization of forage crops have been greatly advanced by silage cutters and blowers, huskers and shredders.

Dairying has been transformed by separators, testers, milking machines, automatic pasteurizers and bottlers, automatic churns, butter workers and by mechanical arrangements for providing water pressure and for handling feed and manure.

Automatic spraying machines have greatly facilitated the care of fruit. Special machinery for dusting cotton and for handling corn forage has been developed to meet emergencies created by the boll weevil and the corn borer. Other miscellaneous improvements include potato digging machines, ditching machines and automatic pumps.

Agricultural production and farm life have been profoundly affected by the automobile and the motor truck. The last two decades have witnessed the adaptation of the gas tractor to almost all kinds of field work and the expansion of uses of stationary engines. Recently there has been a rapid extension of electric power into the countryside and many progressive farm homes have been motorized.

In spite of great progress in the invention of farm machinery, a large part of the world still employs the primitive methods of antiquity. In most of Africa and Asia and parts of Europe mechanization of farming has been retarded by ignorance, inertia, lack of capital and extremely small size of holdings, although the latter difficulty is in some instances overcome by co-operative ownership of farm machinery or by systems of hire. Great Britain, with its comparatively large scale system of agriculture, has been in the forefront of European countries in mechanization of farming. In those parts of continental Europe where large scale farming predominates considerable progress in the adoption of farm machinery has occurred, but such progress was retarded by the breaking up of large estates following the World War. Low wage levels, which prevailed in some continental countries and in South America and South Africa, removed the incentive to the adoption of labor saving devices even where otherwise favorable conditions have obtained.

Canada, the United States and Australasia have held leadership in the adoption of farm

machinery and mechanical power. In 1921 the average value of machinery per farm in Canada was \$935. In the United States, mainly because of the large number of small farms in the South, the average value of implements and machinery per farm in 1925 was only \$423, but the aggregate value was more than two and a half billion dollars and, even allowing for changes in the purchasing power of money, about ten times the value in 1870. The increase in value of machinery in this period was five times the total months of man labor employed in farming. In 1921 tractors were reported by 6.1 percent of occupied farms of Canada, and in 1925 by 7.4 percent of farms in the United States, the latter figure having doubled in five years. Introduction of motor trucks and automobiles, largely for production uses, has been extremely rapid in both countries. In the United States total primary power on farms, other than man power, is estimated to have increased from 1.6 horse power per worker in 1870 to 4.1 in 1920. Of total power utilized in 1924 it is estimated that 61 percent was animal power, 16 percent from tractors, slightly less than 4 percent from motor trucks, 12.5 percent from stationary engines, slightly over 1 percent from windmills and 5.5 percent from electricity.

The agricultural machine, like the industrial, represents a new, more rational combination of the simple components of an operation originally performed by man. It makes possible therefore the employment of motive power and reduces the necessity for intelligent manipulation. In agriculture the adoption of the machine brought with it first an extended use of animal power and later of power generated by steam engines, internal combustion engines and electric motors. It also permits a more perfect execution of many operations or the performance of tasks originally beyond the reach of man because of quantitative or qualitative limitations of the human body. Efficient tillage machinery accomplishes more effective cultivation, resulting in a larger product per acre. Shredders and silage cutters have made possible more efficient utilization of feeds. Mechanical sprayers and dusters are more effective than hand implements in applying safeguards against insect and disease devastation. Pasteurizers and fruit sorters make possible products of higher quality. Hay dryers perform work left originally to the natural forces of the sun and the wind. Yet a most characteristic contribution of machinery to agricultural production still remains to be mentioned: it facilitates

the accomplishment of work in the short span of time when weather conditions are most favorable.

The most important effect of the introduction of farm machinery is economy of human labor. More than thirty years ago it was estimated that in the case of nine principal crops the aggregate saving of farm labor was 79 percent and the saving in cost, 46.3 percent. Very large economies have been made possible by developments since that date. For instance, combines operated by one or two men cut and thresh upward of thirty acres a day, and frequently at less than half the cost for corresponding operations when binders or headers are employed. Economy of farm labor in the United States due to the introduction of farm machines may be roughly measured by the fact that from 1870 to 1920 the acreage of improved land per farm worker increased about 50 percent. Product per worker nearly doubled during that period. Rough comparisons of productivity in the United States and various countries of western Europe indicate a product per man in the United States from two to six times as great. Further allowance, of course, should be made for labor and other costs involved in manufacture of machines.

Although adoption of labor saving devices in agriculture has been generally slower than in manufacturing, the process has been at times sufficiently rapid to result in an embarrassing displacement of labor. In the early thirties of the nineteenth century there were uprisings of farm laborers in the south of England directed against newly introduced threshing machines, and in the comparatively prosperous decade 1850 to 1860 there was considerable unrest in the same area due partly to adoption of machinery. Adoption of farm machinery in the most highly industrialized countries of western Europe was less destructive to the welfare of agricultural labor, by reason of the large outlet furnished by urban industry, than the less extensive adoption in countries of southern Europe where the industrial outlet was more restricted.

The serious agricultural depression in England which began about 1875 was largely the result of competition due to the combination of newly opened grain lands and newly adopted farm machinery in America. On the other hand the introduction of machinery and other improvements tended to mitigate the hardships of the more progressive British farmers. Since 1920 the rapid introduction of tractors, automobiles and other farm machines has aggravated and

prolonged agricultural depression by greatly reducing the demand for feed for horses and mules, while stimulating cultivation of large areas of level semi-arid lands in various countries.

Introduction of farm machinery has resulted in notable geographic shifts toward lands of relatively level topography, particularly to cheap lands of low rainfall in Canada, Australia, the Argentine Republic and the western part of the United States, which could not be economically cultivated under more laborious methods. This tendency has reacted unfavorably on many humid areas unfitted by topography for the extensive introduction of machinery. In the United States these geographic shifts, combined with the cityward movement and certain industrial shifts, have also resulted in important changes in the geographic distribution of political power.

Corresponding to the geographic shifts, profound changes are occurring in systems of farming and of farm organization in various regions. In areas of level topography there is a tendency toward greater mechanization, large scale operation, specialization in production and less dependence on imported casual labor; in areas less favorable to field machinery the tendency is toward development of labor saving methods for non-field operations, adoption of types of field machines better adapted to a rolling terrain, elimination of rougher lands from the farming areas and the development of an agriculture favored by nearness to market.

The whole process of agricultural mechanization combined with the progress of transportation and urbanization has been an important influence in substituting world markets for local markets, and commercial and capitalistic agriculture for self-sufficing farming. Many observers compare the process of agricultural industrialization to the industrial revolution and believe that it will result in the displacement of the domestic system in farming by large capitalistic operating units. Such changes would inevitably involve a profound transformation in the characteristics and status of the agricultural personnel and an equally significant modification of rural social structure.

AGRICULTURAL MACHINERY INDUSTRY. Agricultural implements represent a group of commodities used on the farm and not a group of products manufactured by a single branch of industry. The term "agricultural implements industry," as employed by the United States Census Bureau, excludes enterprises manufacturing farm tractors, vehicles and barn equipment, as well as establishments a minor share of whose output consists of agricultural implements. While in 1927 over 460 million dollars' worth of farm equipment was manufactured in the United States, the value of the total output of the agricultural implements industry did not exceed 203 million dollars. However, in terms of a broader classification, the manufacture of agricultural implements and machines may be considered as a specialized branch of foundry and machine shop work.

As a hand trade the forging of plow irons, sickles, scythes, axes and similar tools is an industry which antedated by centuries the industrial revolution. It was the business of the village blacksmith to make and repair these implements for his neighbors. The improved technique of iron working and the wider markets created by transportation developments resulted in the appearance of small establishments specializing in the production of tools for the agriculturist. This specialization eventually led to improvements in design and to the better adaptation of the implements to the needs of differing localities. Village mechanics or non-specialized manufacturers could not successfully compete with these plants which thus formed the nuclei of a new, growing branch of industry. Plow making was perhaps the first to acquire a separate identity; in the United States it was recognized as a distinct industry even

before 1830. In Pittsburgh, which shortly became the leading center, a factory using steam power manufactured a hundred plows a day as early as 1838. By 1843 Massachusetts boasted of 73 plow makers with an annual output of 60,000 units. The industry was not merely expanding; its technical processes were increasingly mechanized and the individual factories were growing in size. By 1855 John Deere at Moline, Illinois, reached an annual output of over 13,000 steel plows. A similar specialization and improvement could be observed in the manufacture of cradle scythes, shovels and other light implements. In the South several factories were engaged in the exclusive manufacture of Whitney's cotton gins.

A more important stimulus to the development of a factory industry organized on a large scale and producing interchangeable parts came from the invention and rapid adoption of harvesting machinery. Until the late thirties the improvement of agricultural implements was directed at raising the quality of cultivation; after this period the inventions were principally in the nature of labor saving devices. Although 33 English, 2 continental and 22 American inventions of reapers were recorded before 1831, conditions had not yet reached the point where they might be utilized; it was not until the rapid settlement of the western prairies brought about an extreme shortage of labor that a market was created for machines of demonstrated practicability.

Under these exceptionally favorable circumstances a large scale manufacture of harvesting machines grew overnight. McCormick's reaper was not of great practical value until 1845. After trying Cincinnati and Brockport (New York) and finding them unsatisfactory as to location, he established his plant in Chicago in 1847. By 1849 he had 19 local agencies and in 1851 his sales reached the thousand mark. In the following decade six important concerns were organized and by 1879 there were about a hundred relatively large manufacturers of harvesting machines. In the meantime important inventions were crowding the field: the self-rake in 1852, the Marsh harvester in 1857, the wire self-binder in 1874 and the twine self-binder in 1879. With the exception of the last, these inventions superseded neither the original reaper nor one another, but constituted a series of accretions enabling one machine to perform an increasing number of operations. Patent arrangements permitting, it was easy to graft them one upon

another and offer the farmer an increasingly self-sufficient machine. This allowed the expansion of existing plants and the establishment of new plants to feed the enormous demand and did not call for the elimination of those enterprises whose product was becoming obsolete. That is not to say that there were no struggles among manufacturers: patent lawsuits were frequent and protracted, machines of different makes were subjected to competitive field tests to the delight and edification of rural audiences, and competition extended to terms of sale and to the securing of the best local agents by exclusive contracts.

The period of agricultural depression, which lasted from the late seventies until 1896, coupled with the retardation in the occupation of free land, meant a slowing down in the rate of growth of this industry. Also, the perfected harvesting machine had become by this time a complicated contrivance, the manufacture of which was costly and could be carried out efficiently only on a large scale. A terrific jolt to the industry was given by Deering in 1879, when he transferred his plant to Chicago and began manufacturing the twine self-binder. In the struggle which ensued between the twine and the wire self-binders, the number of important manufacturers was reduced from about one hundred to twenty-two. In the following two decades competition was severe: it developed into a real trade war between McCormick and Deering, the two largest producers. Although steel was being used to a much larger extent than before, and minor improvements were being continually made, the sale price of machines was rapidly declining. By the turn of the century the number of firms was reduced to fourteen. In 1902, with the aid of the Morgan interests, five of the largest manufacturers merged to form the International Harvester Company. After purchasing during the next year three more enterprises, the harvester combination found itself in virtually monopolistic control of the harvesting machine field.

In the subsequent period the International Harvester Company proceeded to use its strong position and its abundant supply of liquid funds to acquire control of essential raw materials, to increase its foreign sales, but above all to expand its activities in the manufacture of other lines of farm equipment. The marketing of the product always constituted an important business phase of this industry. The farmers had to be familiarized with the operation of the

"new-fangled" devices; as the machines grew more complicated and expensive it became increasingly necessary for the manufacturers to finance the purchasers; efficient services for the replacement of parts had to be maintained. The pioneers in the industry were forced to build up an entirely new distribution system; neither local mechanics nor general merchants could be relied upon to understand the intricacies of the new machines nor to furnish credit to the farmers. Local agents had to be introduced from the outside and their work supplemented with sales talks and mechanical demonstrations by men directed from the center. In the trade war which developed, agents were tied down by exclusive contracts prohibiting them from dealing in competing machines of other manufacturers; moreover each company attempted to attach to itself as many of such local representatives as possible, thus effectively limiting the retail outlets of other companies. Because credit to retail purchasers was furnished by manufacturers and because competition was severe, the retail sale price of harvesting machines was virtually fixed by their makers. Under these conditions the manufacturers not only owned their production plants but also controlled the large distribution apparatus. The product and its manufacture having been perfected and the sale of harvesting machinery virtually monopolized, costs could be reduced and operations expanded only through the employment of the existing machinery for the sale of an increasing variety of farm equipment.

The acquisition of "new lines" by the harvester combination put the producers in those branches of the industry on the defensive. Among them the consolidation movement had a checkered history. The price cutting of the period 1880-1896 had affected them as well; but combination had not been feasible because of the smaller size and greater numbers. A most important obstacle to agreement in each line was the manufacture of a great variety of implement types scarcely comparable as to quality or cost of production. In spite of this some important consolidations were attempted and achieved. In 1893 the spring tooth harrow combination represented a merger of 21 companies controlling 85 percent of the total output. In the early 1900's an abortive attempt was made to combine the wagon manufacturers. At the same time a plow combine nearly reached completion before it was wrecked by the objections of one or two leading manufacturers. In 1903 a company was organized which controlled half of the national

production of grain drills. In other lines attempts to mitigate the severity of competition led to formation of trade associations which endeavored to induce manufacturers to study their production costs, reduce the variety in similar types of implement produced and to establish a standard costing procedure and thus to formulate indirectly a set of standard minimum prices. The activities of the harvester combination furnished a new incentive to the formation of consolidations in order to take on an increasing number of lines.

Under the circumstances the manufacturers of plows were best able to take effective action. In this branch of industry there were a number of big concerns whose products were in demand during a large part of the year and which had therefore found it advantageous to develop and control a separate marketing organization. They soon found that this organization could also be used for the distribution of an increasingly varied line of implements manufactured by other non-competing concerns. The conditions were thus ripe for taking the next step and controlling the manufacture as well as the distribution of other types of farm implements. This tendency to abandon specialized manufacture, caused as it was by the pressure from the marketing end, has continued to date, two mergers of the same type having occurred during the last year. In the meantime the consent decree entered against the harvester combination in 1918, by which it was ordered to sell three of its five lines of harvesting machines and not to employ more than one agent or representative in any one town, has made the business organization of the industry somewhat more homogeneous. It increasingly tends to consist of a number of large, full line houses with a greater number of smaller specialized manufacturers compelled to cooperate with manufacturers of other non-competing lines in marketing their output.

The past quarter century has witnessed an important addition to sources of motive power on the farm. Even before 1900 stationary internal combustion engines were employed in agriculture, largely in connection with threshing. On the very large farms steam power was used for pulling plows, the energy at first being transmitted to the plow through a system of cables and later by attaching the steam engine to the plow. From these unpromising beginnings the early tractors were developed in the 1900's. Although lighter than the steam engine they were still very heavy, called for the use of

extremely large agricultural implements and were practicable only where cultivation of the soil was conducted on a large scale. By 1910, however, internal combustion engineers devised smaller, lighter tractors, and in 1914, 3000 units of this type were sold by American manufacturers. The war further encouraged the manufacture of tractors. The diversion of man power to war uses, coupled with the need for increased agricultural production, stimulated further mechanization of farm operations. The equipment used in manufacturing war munitions proved easily adaptable to the production of tractors, so that with the termination of the war a large amount of equipment became available. The post-war period brought a further improvement in tractor design: by 1925 general purpose small tractors had become both practicable and popular. Since tractors have several other important uses, their manufacture is not generally considered a part of the agricultural machinery industry; because of the nature of the product as well as of the manufacturing processes involved it is more nearly a branch of the automobile industry. However, it interlocks with the agricultural machinery industry at more points than one: large manufacturers of agricultural equipment, in conformity with the tendency to carry a full line, produce tractors just as they previously manufactured stationary internal combustion engines and still continue to manufacture horse drawn wagons; tractor manufacturers tend to expand into the production of plows; finally the use of the tractor is influencing, and is bound to influence in the future, the design of agricultural implements in connection with which the tractor is employed.

The United States is by far the largest producer of agricultural equipment. Because of its possession of the essential raw materials and technical skill and because of the existence of a rapidly expanding domestic market, the industry soon developed to the point where it was exporting its products to foreign markets. The most important of these were the countries of the New World in which agriculture conducted on a large scale was rapidly preempting hitherto virgin land, but which were not sufficiently advanced industrially to make feasible a domestic manufacture of the heavier and costlier agricultural machines. Argentina, Canada, Russia, France, Australasia and British South Africa together absorbed very nearly the entire American exports. The characteristically American export product is the harvesting machine; since

the war farm tractors have also been exported on a large scale. The International Harvester Company expanded its foreign business to a point which called for the organization of an extensive chain of foreign branch houses and the establishment of plants in Germany, Russia, Sweden, France and Canada. Smaller companies took care of their exports by establishing permanent connections with foreign jobbers.

The table below represents a statistical summary, based on census and Department of Commerce data, of the historical development of the industry in the United States.

In addition to the United States the industry has also reached an impressive magnitude in the United Kingdom and Germany. The early development of the iron and steel industry and of the engineering trades, as well as her dominant position in world commerce, fitted England to become an important producer of agricultural machinery; the relative insignificance of English agriculture and the virtual monopolization by America of the production of harvesting machines were of course negative factors. England began early to manufacture improved plows on a considerable scale and developed a large export

YEARS	AGRICULTURAL IMPLEMENTS INDUSTRY*			EXPORTS OF AGRICULTURAL IMPLEMENTS† (IN \$1,000,000)	FARM TRACTORS

* This industry embraces only establishments which were engaged primarily in the manufacture of implements of cultivation, of harvesting machinery, of machines for preparing crops for market or use and of miscellaneous small agricultural implements. For the period 1899-1919 the data cover only establishments with an annual output of \$500 or more. For the period 1921-27 the data cover establishments with an annual output of \$5000 or more.

† In addition to the items enumerated above, this includes dairy machinery, farm tractors and windmills. For the years previous to 1919 the exports are given for fiscal years ending June 30. The figure for 1869 is for the fiscal year ending June 30, 1870.

‡ This is an average for the period 1910-14.

The manufacture of farm equipment for local needs is found in practically every country. It is usually confined, however, to the production of cheaper, lighter implements and to the adaptation of foreign models to peculiar local needs. The production of separate lines of farm equipment is extensively developed in some countries. Sweden is an important producer of cream separators and exports this product to the four corners of the earth. The manufacture of tractors was stimulated recently in France and Italy in order to reduce the need for imports and to obtain a lower priced product. In Australia and New Zealand a local industry developed, which attempted to adapt agricultural implements to the peculiarities of the agricultural processes of that continent.

in this line. Heavier machines were manufactured by works not specializing in farm equipment; the largest of them depended upon the Dominion and Argentine markets for the disposal of the greater part of their output. At the same time England imported 30 percent of the equipment used on its own farms; after the war this proportion increased due to the growing popularity of American tractors. Because of the inroads of foreign competition the industry was at the outbreak of the war in a depressed condition; it has been in a worse plight since the beginning of the last decade. During this period it has shown a tendency to form combinations; nearly all of the largest firms and those of the highest standing are now members of one or another of a small number of groups. The trade

association of the agricultural engineering industry is promoting standard cost keeping systems and the regulation of price and discounts through "sympathetic agreements."

In Germany the industry developed in the second half of the nineteenth century through the attempts to adapt English and American implements to a variety of local needs. An important stimulus was also found in the proximity of large foreign markets, such as Russia and the Balkan countries, which were in obvious need both of cheaper implements and longer credit terms than could be provided by English and American exporters. In the late seventies the general industrial development of the country and the necessity for the intensification of agriculture as a protection against overseas competition encouraged the further growth of this branch of manufacture. The organization in 1883 of the Deutsche Landwirtschafts-Gesellschaft, which carried on an active educational campaign among farmers, and the multiplication of cooperative credit and purchase societies have tended to enlarge the absorption capacity of the domestic market. By 1900 there were in Germany, according to Gustav Fischer's estimate, 1200 plants employing 23,000 persons. Plows constituted the most important product, some of the German makes being well liked in many European countries and in South America. Since 1902 the German industry has lived under the regime of protection, so that by 1906 exports exceeded imports; before the outbreak of the war two thirds of the total output was exported and fully a half of this was sold to Russia. The war has resulted in an increased output for domestic uses and in a reorganization of the manufacturing processes to permit mass production and greater standardization of implement types. With the termination of the war many war munitions plants have turned to the production of agricultural equipment; the Krupp plant, for instance, has almost tripled its production in this line. It is estimated that the German industry in 1920 numbered 800 plants employing 75,000 persons. More recently Germany has considerably enlarged its production of farm tractors, and in 1928 for the first time exports of tractors exceeded imports.

The fortunes of the agricultural machinery industry are very closely related to the prosperity of agriculture. The world wide agricultural depression which has prevailed since the war and the elimination of Russia as a large importing country have put the industry in an

unsatisfactory condition. A greater standardization of simple implements, the development of new types of machines better adapted to use with tractors and designed to mechanize the performance of tasks still done by hand (cotton pickers, improved sugar cane machines), business reorganization which will enable single concerns to manufacture and sell more or less complete outfits of farm equipment, are present day tendencies which are expected to restore more normal conditions in the industry. The application of electricity to farming, still in the experimental stage, is an unknown factor and may completely revolutionize the industry.

AGRICULTURAL MARKETING.

HISTORY. It is only in relatively recent years that the always vague and shifting line of demarcation between the marketing of agricultural and of non-agricultural products has become significant. The sheep or the corn which the early cultivator of the soil bartered for the copper or fine clay of a neighboring group was but one of a few exchangeable products, hardly to be distinguished in method of disposition from the weapons of wood or metal which might find their way into the channels of trade. With the growth of city civilizations trade in foodstuffs became a somewhat specialized ac-

tivity, but the techniques of marketing wheat or spices, silks or fine gems, are essentially similar. The product of agriculture is but slightly differentiated in methods of distribution from the product of a small scale, hand industry.

The recorded history of marketing in the ancient world deals chiefly with the foreign commerce of the great city centers of population in Egypt, Babylon, India, China, Greece and Rome. At all times a large share of this commerce was in foodstuffs and other agricultural products. Athens exported olive oil, figs and honey. But Athens was not an agricultural state and had to import half her food supply. Her wheat, for instance, came largely from southern Russia by way of the Black Sea. The data are lacking, however, to show us just how these primitive Russian farmers marketed their wheat and in what form they took their pay. The Code of Hammurabi shows clearly that Babylon carried on a vast commerce as early as 2300 B.C. Silver and gold were used for money, banking functions were carried on by the merchants, and wheat, wines, sheep and wool were among the agricultural products exported. Egypt for many centuries was shipping linen, paper and wheat to neighboring lands. Rome's commerce is well known, especially after the first century of the empire. This was the period of the "hygienic markets and splendid shops of Rome," as it was the period of great prosperity of Roman agriculture and stock raising. There was a tremendous development of trade, both wholesale and retail. Safe and easy communication was established with all nearby countries; the Mediterranean and Black seas were regarded as Roman lakes; the great rivers of western Europe and the Nile were highways for Roman commerce; caravans of camels traversed all southern Asia and northern Africa; the sea route was used to India, Arabia and the north coast of Europe. Regular commercial relations were established with China, India, Africa (northern, central and southern), central Asia, southern Russia, Germany, Norway, Sweden, Britain, Gaul, Spain. Into the shops of Rome came metals, precious woods, precious stones, amber, silk, furs, as well as luxuries for the table from the farms of the world. From the fields of Italy came poultry, cattle, wheat, olives and wines.

With the breaking of these lines of trade in the disturbed years of the early Middle Ages and the return to community self-sufficiency

in the manorial system, the marketing of agricultural products became again largely a local affair. Most farming before 1300, when that system reached its highest development, was largely self-sufficient and involved very little actual bartering or buying and selling. But if the manor produced most of its own foodstuffs it was also independent of outside communities for the supply of most of its clothes, furniture, weapons and instruments of production. This self-sufficiency was only relative and of short duration. The spices and luxuries of the East slowly filtered into Europe through the barriers of difficult transportation and hostile separated communities. Agricultural products played their part in the reviving trade. In the great fairs to which foreign merchants brought their wares, and in the lesser markets which provided a means of local exchange, corn and wool and wine were traded for the product of the city guildsman or the luxuries of a far land.

Periodic fairs, large and small, were the most important marketing mechanism of the Middle Ages. A considerable amount of intra-manorial exchange was accomplished in the payment of the various manorial dues, but in good years there was always a surplus to be sold at the local market and thence carried by the itinerant trader to the larger fair. These institutions apparently grew up first as religious rather than as commercial activities. They usually began in religious assemblies about monasteries or shrines on feast days. Said one French writer: "There is no great festival without a fair; no fair without a festival." The religious element remained important; but at the great fairs of Bordeaux and Champagne, or St. Giles and St. Botolph, it was the commercial opportunity that was dominant throughout the days or weeks that merchants and customers were assembled. And as with the increase of population, the facilitation of transport and the growth of cities the periodic fair was supplemented and finally largely supplanted by regular local markets, a complex commercial system developed.

Even this relatively direct form of marketing involved an elaborate organization of merchants and traders, speculators and lenders of money; it resulted in the formation of commercial leagues and the establishment of foreign trading centers. As cities grew in size and influence, the principal role in the marketing mechanism passed from the trader gathering surplus grain

from one local market after another, to the merchant and his factor bargaining for the control of the next year's crop from a whole region. And slowly, throughout the seventeenth and eighteenth centuries, the public markets of the cities were replaced by the wholesale exchange and the retailer with his permanent shop and stock of goods on sale every business day. The same process of elaboration of the marketing mechanism was going on in the textile trades or in the woolen industries. The disorganization of such changes was more noticeable in regard to agriculture, for the danger of famine or dearth was ever in the background. Local supplies were drawn to the cities, and as in modern times agricultural surpluses frequently existed alongside of agricultural dearths. Governments unsuccessfully attempted to prevent dearth by controlling exportation, and the trader was more and more successful in freeing himself from governmental supervision.

Not only were changes in the methods of distribution of agricultural and of manufactured products occurring simultaneously and in similar directions during the seventeenth and eighteenth centuries; in many countries there was taking place an "agrarian revolution" which was bringing into prominence new agricultural products and a new organization of agricultural production. The changes were in line with the increasingly commercial emphasis of society. But the adjustment was of short duration. By the end of the eighteenth century there had begun that process of industrialization which so altered the position of agriculture in the economic order. Great as have been the transformations in methods of distribution of agricultural products whenever city civilizations have arisen, there has never until the past century been a time when agricultural products were not the most important articles of commerce. Now, although the food supply is still basic, society is timed to the furnaces of the steel mills rather than to the harvest and the fruit crop, and the complexities of the financial superstructure are greater than they have ever been before.

Not only must the agriculturist move in the shadow of the industrial system, but all his contacts with the commercial and industrial system have become more direct and immediate. The farmer no longer lives in relative isolation and self-sufficiency, relying upon the merchant to gather his bit of surplus grain; he must now plan for the market—indeed his

whole method of living must be directed toward the commercial disposition of his products. An increasing complexity of the market mechanism has resulted, for this system into which the farmer must fit includes also the great grain and raw material producing areas of the new continents or of the "backward countries." It is a system in which the development of world exchanges first facilitates and then enforces competition between the staple products of the smallest farm in the United States and the largest ranch in Australia.

With all its increasing complexity the system is still inadequate to effect a smooth or stable adjustment of agriculture to the economic order. Even where large scale machine methods and modern systems of accounting are applied to agriculture, its dissimilarities to other industries are striking. It is, in the first place, not one but many industries, where one farmer may produce staple food products for a world market, industrial raw materials for a distant industry and dairy products or fresh vegetables for the nearby urban communities. Even with specialization there are definite limits to the consolidation of agricultural units. More important is the almost insuperable difficulty of regulating the quantities of agricultural products. It is not merely that weather is uncertain and production seasonal but that there is no method of controlling the output of the innumerable small producers throughout the world. The maladjustments which result from these difficulties press almost equally as hard upon groups which remain outside the industrial-capitalistic system as upon those which have been drawn almost entirely within it.

Agencies and methods of organization have grown up from within and from without the system of agricultural marketing. Railroad rates and automobile costs, the concentration of the milling and sugar industries and the demands of textile manufacturers set a pattern to which the system of agricultural marketing must conform, while the development of world commodity exchanges, of cooperative marketing, of methods of refrigeration and storage bring stabilization and pattern from within. The pattern is yet incomplete and constantly shifting, but its main outlines can be traced.

UNITED STATES. In the United States agriculture is now quite generally on a commercial basis, that is, the farmer sells most of what he produces and buys most of what he consumes.

The marketing process consists of six fundamental operations—production, transportation, storage, credit, risk bearing and sale.

To perform the various marketing services implied by these functions many different types of middlemen have been evolved. Transportation is of considerable importance in the United States, where the average haul of food is about one thousand miles. The railroads are still the most important transportation agency for agriculture as for other industries. Indeed the development of methods of refrigeration has increased their importance. But it is also true that automobile transport has had far reaching effects on agricultural marketing. The truck and the paved road have increased the radius of influence of local markets and made possible new utilizations of land. They have reduced not only the farmer's social isolation but his economic remoteness, with results which cannot yet be measured.

Storage in the United States has made enormous progress in the last fifty years, particularly in the fields requiring artificial refrigeration. Millions of tons of foods are now stored in the summer awaiting the autumn and winter demands. The quality of the food remains good; the price is greatly stabilized to the farmer's advantage. Such storage is feasible for butter, eggs, poultry, fresh meats, cream and many kinds of fruits and vegetables. Dry storage is provided for grain in the form of country and terminal elevators. Warm storage takes care of such foodstuffs as bananas, sweet potatoes and white potatoes.

Although the furnishing of credit has become one of the most specialized of modern services, the farmer is not entirely dependent upon the ordinary commercial agencies. In most countries governments have provided special systems of agricultural credit (*q.v.*). Risk bearing may be distributed by the farmer in many cases by means of insurance. Risk is also lessened by a wise treatment of the fundamental factors of uncertainty, many of which are subject to human control. Grading and standardizing are doing much to lessen business disputes, particularly disputes over the rejection of consigned goods. Better quality production, more thorough culling, better packaging and loading—all these activities are lessening the risks of loss and damage in transit. There remain, however, many economic risks which cannot be eliminated.

The sale of any product is today a highly

specialized activity. The relationships of the various middlemen who are concerned are constantly shifting with new methods of production and distribution. The usual classification of sellers has been the threefold one of wholesaler, jobber and retailer. The functions of wholesaler and jobber, both of whom buy in large quantities and sell in smaller amounts, tend to overlap. In most industries both are gradually being replaced by other, usually more specialized, types of distributors. This tendency is apparent in the marketing of agricultural products, although it operates more slowly than in the case of large scale industries.

Among the newer types of middlemen, brokers and commission merchants are dealers who act as agents between buyers and sellers, but do not take title to the goods. Brokerage fees usually run from 1 to 2 percent; commissions from 1 to 15 percent of the selling price. The commission merchant, receiving the goods on consignment, does a certain amount of physical handling. The broker usually has no handling of the goods, but finds buyers by means of interviews, letters or wire. As commodities become better graded and standardized the number of brokers increases, while that of commission merchants decreases. Livestock, wool and wheat are still sold almost entirely by commission merchants, for personal inspection before purchase is here necessary to determine actual values.

One of the more important of the new agencies which are introducing economies into the distribution of agricultural products is cooperative marketing. It has achieved substantial success in grain, dairy products, livestock, fruits and vegetables, and nuts. In grain the five thousand farmers' elevators were and are successful in overcoming certain trade abuses. In the dairy industry the local creameries or cheese factories have now in many sections improved the quality of their products, standardized them and moved them in large quantities, so that savings have been made, consumer demand increased and prices thereby strengthened. The Minnesota creameries by cooperating and shipping butter in car lots, rather than in less than car lots, were able to save ten thousand dollars a week in freight alone.

Auctions provide a means of distribution for some products. They are used extensively in most of the large cities for the sale of citrus fruits, grapes and certain deciduous fruits. This affords a much cheaper method than the old

fashioned commission merchant. In New York attempts have been made to use the auction in the sale of eggs, and the method is slowly growing in favor. The farmers of Kern County, California, have for many years made successful use of the auction in marketing hogs, competing buyers coming from San Francisco and Los Angeles. The cost of this service is very low.

Chain stores have entered the field of selling fresh fruits and vegetables, with notable changes in our marketing system. Their policy is to purchase in large volume and to demand standardized products of relatively high quality. Such purchases are more and more made through cooperative organizations of producers.

Roadside markets are the simplest form of direct marketing used by the farmer. With the coming of good roads and the automobile the farmers near large cities and the smaller mill towns find customers at their door for their fresh fruits and vegetables, eggs, flowers and various other products. With unpaid family labor and long hours the farmer can move a large volume of produce in this way with negligible expense. An increasing amount of produce is also distributed by means of parcel post.

The general pattern of agricultural marketing is set by these agencies and methods. In addition special mechanisms have been developed for marketing each farm commodity. The better standardized commodities are now bought and sold on organized commodity exchanges. This is true of grains, cotton, butter and eggs, and certain pork products (mess pork, ribs, lard). In these products there is future trading and hence continuous price quotations. At the other extreme are found the perishable fruits and vegetables such as peaches, strawberries and tomatoes, which have no organized markets and no official price quotations. Between these two extremes come the semi-perishable commodities such as potatoes and apples, which can be stored but not beyond one season. There is no organized market for such commodities, but a large number of central markets.

Grain and cotton may be taken as types of the standard commodities moving freely in the channels of world commerce. Wheat, grown on two million farms in forty-four states, moves first to the nearest railroad station or flour mill. Here it is sold for cash, usually to the country elevator. Such elevators are of four types: independent (owned by local business man); farmers'; line (owned by corporation at central markets); mill. If the grain goes to a farmers'

elevator (and 56 percent of all grain reaching Chicago comes from farmers' elevators), the routine is as follows: the farmer is paid with money borrowed from the bank or advanced by the commission merchant at the central market. Grain paper, so-called, is standard liquid security for bank loans at the lowest current rates. Bills of lading or warehouse receipts constitute the usual collateral for such credit. The grain in the country elevator is either consigned, or is sold by wire "to arrive," that is, for deferred shipment, the price and the time of shipment being stipulated in the bid. Arrived at the terminal market, the grain is sold to a terminal elevator owner, an exporter, a miller or some of the grain industries. The buyer hedges himself against loss from price decline by selling a future on the grain exchange, speculators being the chief buyers of futures. The effect of this hedging or price insurance is to enable the market in the fall to absorb without a price depression millions of bushels of grain dumped day after day.

Cotton may be compared with wheat: both are liquid commodities; both move away from the farms into the channels of world commerce; both are financed at low cost because of the standard trade documents involved; both are subject to federal grading and may be stored for long periods with little deterioration; both are subject to future trading on the organized exchanges of Europe and America; both have continuous market quotations. In contrast to cotton or wheat is corn. For while corn is a staple commodity, 80 percent of that produced in the United States is consumed on the farm. Indeed it is estimated that farmers use 40 percent of all agricultural products as raw material for further production.

Livestock is marketed in an entirely different manner from that used in connection with cotton and wheat. While a certain amount is prepared on the farm or by local butchers, about 60 percent of all the meat slaughtering is done in the large central markets which are served by public stockyards. Farmers may sell to a local livestock buyer who consigns to a commission merchant at the stockyards, or the farmer may consign his own car to the same agency. At the stockyards the commission merchant faces five types of buyers: the packers; city butchers; order buyers (who buy to ship to another market); speculators (who buy to sell again on the same market); buyers of stockers and feeders (who buy stock not yet "fin-

ished," but which must be shipped back to feeders in the country). Two significant changes in recent years have broken into this routine of marketing. Cooperative marketing, through local livestock shipping associations, assembles and ships in car lots for the farmer at a minimum of cost for the service; at all the big packing centers there are now cooperative agencies to sell in competition with the regular commission merchants. The second change is the so-called direct packer buying, a new method whereby packers send buyers to the country and buy from farmers. In either case the price quotations established at the stockyards are the only price barometer the farmer has.

Milk is by far the most valuable product of American agriculture. Whole milk for city consumption is now largely handled by farmers' cooperative dairy associations doing collective bargaining with the city distributors. The two milk by-products, butter and cheese, account for about 50 percent of the milk produced. These two things are handled quite generally by local cooperative concerns, federated for purposes of inspection, grading, standardizing and better merchandising.

The marketing of fruits and vegetables is especially confused, except in those specialized areas where cooperative organizations have standardized the product and put it on the market under their own brand. The markets suffer from alternation between oversupply and dearth, and there is no adequate price barometer to serve as a guide to production.

In recent years federal regulation of marketing has been introduced to cure trade abuses and to promote the interests of the producer. The federal government has established grades and standards for about one hundred commodities, and also provides for optional shipping point and terminal inspection where made necessary by the volume of business. In addition to the regular research studies and administrative activities of the United States Department of Agriculture and its Bureau of Agricultural Economics in the field of marketing, there have been four outstanding regulative acts in recent years: the United States Warehouse Act of 1916, aiming to improve storage and to provide cheaper credit by means of the warehouse receipt; the Grain Standards Act of 1916, a law providing uniform federal grades for grain and also federal supervision of all state and local grain inspection systems; the Packers and Stockyards Act of 1921, giving the secretary

of agriculture power to supervise and regulate the packers and the stockyard companies; the Grain Futures Act of 1922, giving the secretary of agriculture authority and power to supervise and regulate grain futures markets and to prevent manipulation and corners. In comparison with the past, however, the freedom of internal trade is the distinguishing feature of our agricultural marketing system.

JAMES E. BOYLE

EUROPE. The great industrial development of the early nineteenth century in Europe was confined to certain clearly defined regions and, while agriculture in the surrounding countries was quick to react to the stimulus of the new markets, national boundaries and inadequate transport facilities caused the more distant peasant communities to be left undisturbed for a long time by the new circumstances. No intricate system of marketing of produce within the countries themselves was necessary. Organization of an export trade in food from the rural countries to the industrialized countries was of slow growth. By the end of the century, however, marketing systems had been evolved to draw upon the surplus supplies of even the more backward agricultural communities.

More progressive marketing methods have since been adopted, but century old practices continue to exist side by side with modern developments; even the upheaval in the marketing of foodstuffs caused by the war of 1914-18 did not completely abolish traditional methods. In the last two or three decades in the export trade the marketing of dairy products has been the most progressive. With regard to products sold in home markets, the organization of the marketing of liquid milk has undergone the greatest changes. The latter has been rendered necessary, first, by the increasing demands for fresh milk in urban areas and, second, by the continually rising hygienic standards which are being set for the production and handling of the milk. Progress in the marketing of exported dairy produce may be very largely due to the example and high standard set on the British market by the Danish butter producers.

Factors which influence marketing organization over a whole continent of more than twenty independent nations are so numerous as almost to defy analysis. In general, systems of disposal of produce by farmers may be said to differ, first, according to the nature of the

commodity; second, according to the nature of the trade, whether for local consumption, for distant consumption within the national boundaries or for export; and third, according to the importance of the commodity in the farm economy. Close attention is often given to the method of disposal of the major produce of the farm, but the minor produce may be "dumped" upon the readiest market.

The direct retailing of produce by the individual farmer to the consumer, presumably the most elementary method of disposal, continues to some extent for most commodities which do not require elaborate preparation, e.g. milk, butter, eggs and fresh vegetables. A rapidly decreasing proportion of farm production finds its outlet in this way. Street markets, operating under increasingly stringent regulations; hawking from door to door; and, to a much less extent, parcel post are the means by which produce is brought direct to the consumer.

So far as can be estimated, the largest proportion of all produce is sold by farmers in the wholesale market. Neglecting for the moment the farmers' cooperative associations, produce is disposed of by farmers to the wholesale and retail traders in three main ways: sale outright in local markets either by private bargain or by auction; sale in distant markets by agents acting for the farmer and paid by commission; and sale on a period contract to one firm. Sales of cattle and sheep by farmers take place mainly in local auction markets, owned and regulated either by municipalities or by auctioneers. Grain is sold by private bargain to merchants. Direct selling to millers has declined owing to the concentration of the milling industry. The larger proportion of fresh vegetables is consigned to distant markets and sold there on commission, but the method of sale varies according to the distance of the farms from a large consuming center. The method of sale on contract to wholesale and retail firms and to factories is increasing with certain kinds of produce. Sugar beet is universally sold on contract to factories; fresh fruit for preserves, milk either for the liquid trade or for manufacture, and eggs show a marked tendency toward this method.

The more recent developments of agricultural marketing center around the growth of the farmers' cooperative movement and the interest of governments in the prosperity of agriculture. Farmers' cooperative societies in some forms have existed for a very long time in

European countries. Generally speaking, cooperation among farmers for the sale of their produce is more recent than credit and purchase associations. In most of the European countries there has, however, been considerable development in selling societies. In some countries, in almost all kinds of produce from milk products, pig products, eggs and wine to livestock and cereals, progress has been very marked. Cooperative selling by farmers of liquid milk, fresh fruit and vegetables appears to have made less general advance, but abundant examples of successful efforts exist. Among the raw materials for industry, sale and export of flax from the eastern Baltic states are on a cooperative basis, and the organization of wool growers in England and Scotland has shown recent development.

The cooperative movement has the active support, in greater or less degree, of the governments of the various countries. In Soviet Russia and Finland universal cooperative selling in agriculture is the definite policy of the existing governments. Apart from these countries Denmark appears to have the most highly developed cooperative organization in Europe. It has been estimated that nearly 90 percent of the Danish farmers are members of cooperative dairies, while 70 percent disposed of pigs through cooperative abattoirs (1925).

An important development has been the federation of cooperative societies for the export of produce. Denmark furnished the best example of consistent success in this direction for many years, but other European countries are similarly organized. Approximately 40 percent of the butter leaving Denmark is exported by fourteen large export associations serving 580 affiliated local societies (1925). Cooperative societies for export of butter are also important in Russia, Netherlands, Finland, Esthonia and Latvia. The federations of Swiss milk producers very largely control the export of all cheese from Switzerland, while one of their federations is directly engaged in export trade. A very large part of the export of eggs from Denmark is in the hands of a cooperative egg export association with which about 550 local egg collecting stations are affiliated (1925). Other countries from which eggs are exported cooperatively on a large scale are the Netherlands, Russia and Poland. Other commodities in the export of which farmers' cooperative associations exercise considerable influence are bacon from Denmark, flax from the eastern Baltic coun-

tries and currants and raisins from Greece.

A feature of the cooperative marketing of agricultural products to which considerable attention is being directed is the growth of direct trading relations between the agricultural co-operative organizations and the consumers' co-operative societies. As far back as 1896 the Congress of the International Cooperative Alliance endeavored to foster trade relations. More recently encouragement has been given to this movement at the World Economic Conference (1927) by a clause in the general resolution on agriculture, and by a special resolution expanding the views of the conference on this question.

The war time restrictions of governments upon the sale of agricultural produce have almost entirely disappeared, but the active interest of governments in the trade in agricultural produce is manifested in many ways. Government monopolies in tobacco exist in several countries, and flax is a government monopoly in Latvia. There are other countries in which the governments have had a direct participation in the trade in agricultural produce, as for example in the case of grain in Norway and of the recently abolished wheat monopoly in Switzerland; but how far any of this is of a reasonably permanent character it is impossible to say.

Apart from direct state trading all governments are giving increased attention to the problems of the marketing of produce. The encouragement of cooperative effort has already been referred to. Official grading of farm produce for export has been in operation in certain European countries for many years, but since the war of 1914-18 more care has been exercised in this direction, together with the establishment of "official marks," especially in countries exporting dairy produce and eggs. Official grading and marking of produce by a "national mark" for the home market has recently been made the object of schemes developed by the Ministry of Agriculture for England and Wales and the Department of Agriculture for Scotland.

Farmers also obtain increased benefits in marketing from other state activities such as the prevention of fraudulent dealing, the control of freight charges, the issue of market intelligence concerning supplies and prices, and the expansion of facilities for economic research in marketing.

AGRICULTURAL POLICY. From ancient times to the present the policies of government toward agriculture have necessarily occupied a large place in the attention of statesmen, since agricultural products furnish not only the subsistence of the people but also a considerable part of the raw materials of industry and are a major item of commerce. In a broad way such policies may be grouped under three heads. First is the extreme position that agriculture should be fostered as a prime source of national strength. Second, and at the opposite extreme, is the policy of complete or virtual disregard of agriculture and dependence on imported food and raw materials of industry. Between these two extremes we find a third policy which looks in a general way toward self-sufficiency. The

country which follows this policy aims to supply in the main its own agricultural needs but does not seek to derive any considerable part of its national income from the export of agricultural surpluses.

A highly developed agricultural or industrial policy is more likely to be established at the present time when adequate transportation facilities or great scientific and technical knowledge have made extreme types of economic specialization feasible. It is also evident that small countries will probably find themselves forced into rather intensive development of a single line of production, or at best a narrow range of specialization, whereas countries of broad geographic extent and considerable diversity of natural resources find a high degree of self-sufficiency both natural and profitable. The British Isles probably present the best illustration of highly developed industrial growth and comparative indifference to agriculture. Economic resources and the momentum of early development create so great a comparative advantage in the fields of mining, manufacture and trade as to make any thoroughgoing policy of agricultural stimulation impracticable. Great Britain typifies the most extreme development of an industrialized country content to be dependent upon overseas producers for the bulk of her agricultural supplies, feeling secure in the possession of a powerful navy, ample merchant marine, a highly developed trade organization and a dominant financial position. The World War so shook the bases of this confidence as to start an almost hysterical agitation for the rehabilitation of agriculture even to the extent, as some of the extremists demanded, of self-sufficiency in the staples of subsistence. The practical result has been some liberalization in land policy, a stimulus to agricultural education, protective legislation for the agricultural laborer and a somewhat more generous encouragement of husbandry in general. But even post-war Britain, with the vivid memory of threatened famine under conditions of submarine warfare, has found it impracticable to do much toward reviving an agricultural industry which had been waning since the coming of the industrial revolution. To a certain extent Great Britain seeks to effect a favorable exchange situation between her own industrial and commercial enterprise and the agricultural predisposition of the scattered members of the empire. Actually, however, England follows the current of economic rather than political affilia-

tion and finds that Argentinian beef and Danish butter fit into this system quite as well as Canadian wheat and New Zealand lamb.

In Germany industrial development was intensive in the western provinces in the late decades of the nineteenth century, but the east embraced a large agricultural domain whose representatives attained a potentially dominant position under the empire. The agrarianism of the Prussian *Junker* was that of one who was both militarist and landlord, and he was working for his own personal interests at the same time that he was providing his country with an internal supply of bread grain in case of war.

It is somewhat paradoxical that, although the dominance of the *Junker* has now been superseded by the dominance of the western industrialist, even post-war German policy favors agricultural development. This is a result of the post-war industrial and commercial position, which has been unfavorable to the securing of imports of food and agricultural raw materials on advantageous terms. Hence it has appeared necessary to resort to agricultural tariffs and other devices to stimulate domestic supplies. This line of action, however, must be regarded as a temporary expedient rather than a permanent adjustment. Germany's agricultural resources, none too ample in the days of the empire, were seriously curtailed in the fixing of national boundaries under the Treaty of Versailles, and it seems inevitable that the ultimate realization of the country's maximum economic potentialities must be dependent chiefly on her industrial and commercial development. This means the reestablishment of advantageous reciprocal relations with countries more favorably circumstanced for agricultural specialization. In terms of geographic proximity and natural resources Russia is capable of playing such a role. But Russia's sluggish general economic recovery and the disparity between an increase in agricultural productivity and the growth of population, with the accompanying elevation of the standard of living, makes this solution improbable at present.

It seems self-evident that Russia's resources foreordain her to an agricultural future which will overshadow her industrial achievement, considerable though that may be. Imperial Russia manifested considerable concern in providing transportation facilities and in furthering manufacturing and commercial development during the closing years of the nineteenth century and in the twentieth century before the

outbreak of the World War. Although the Revolution of 1905 forced the czarist government to recognize that something had to be done to relieve the peasants, little was done to facilitate in any real sense the development of Russia's agricultural potentialities. The policy inaugurated by Stolypin contemplated an improvement of agricultural technique and a development of agricultural resources through colonization of Siberia. The prosecution of this policy was interrupted first by the World War and then by the Revolution of 1917, which brought in its wake expropriation of land belonging to large estates and its distribution, with insignificant exceptions, among the peasants.

After the stormy period of 1918-21 the Soviet regime set itself definitely to rebuilding the economic life of Russia out of its own resources. This has meant a liberal policy toward the peasant in order to expand agricultural production as fully as possible. The principal result has been to strengthen the rich peasants, the *kulaks*, to a point which has embarrassed the Communist party. Hence in 1928 it felt constrained to put more emphasis on the policy of "agrarian socialization." An important feature of this program is the development of large scale collectivist farms designed to increase the agricultural product at the disposal of the government, to demonstrate the technical superiority of this mode of farming and to provide profitable employment for the poor peasants. On the whole the Soviet government is committed to a policy of fostering the development of manufacturing industries which would make Russia economically self-sufficient. However, the immediate need for an agricultural export surplus and the fact that the majority of the population is still engaged in farming makes inevitable for the near future a policy of continuous stimulation of agricultural production.

Italy has recently entered upon a program intended to increase agricultural productivity. Agricultural education, in comparison with popular education, is quite impressive, and considerable effort has also been made to set up a system of rural finance and cooperative organizations. Since the war a vigorous attempt has been made to increase the home supply of bread grains in order to strengthen her position in international trade. Although the movement has thus far been disappointing, an even more ambitious program for the future is now being pushed forward. It contemplates large outlays

of public funds and an aggressive, almost coercive, stimulation of private enterprise to reclaim several million acres of additional lands as well as the more intensive cultivation of those already in use. The purpose of this policy is to assure Italy's independence of wheat imports even though it is admitted that wheat from Canada or one of the other newer countries would be far less costly. The program is defended on the ground that the dense population of the country provides a surplus of labor which cannot be applied to the production of export commodities sufficient to give the nation the purchasing power necessary for the importation of the requisite supply of wheat. Fascist policy emphasizes agricultural self-sufficiency chiefly because of the pressure of population and an unwillingness to accept the alternatives of emigration or of birth control. This suggests that the present policy of agricultural stimulation will be continued.

As compared with the rest of western Europe, Denmark stands out as distinctly agrarian. During the last seventy-five years, while industrialism has been growing in the neighboring countries, Denmark, admitting her poverty in industrial resources, has applied herself with the utmost skill and diligence to the intensive development of her agriculture. This policy, both democratic and practical, has built up a remarkable system of agricultural education and fitted commercial, banking and transportation services to the needs of the agricultural population. Recently there has been a considerable increase in the number of the urban population engaged in those branches of manufacture which represent a more intensive utilization of agricultural produce. Because land resources are already so fully employed that any increase in population cannot be used effectively in primary production, it has become a concern of the government to carry the processing of these farm products as far as possible and to provide the services incidental to this basic agricultural industry as fully as possible within the country itself. The agrarianism of Denmark thus has a distinctly different character from that of a younger sparsely settled country following an intensive line of agriculture and exporting the product in its raw state or with a minimum of processing.

Other countries which have definite, though less developed, agricultural policies may be found in Europe, particularly those that are in the Baltic (Latvia, Esthonia) and in the

Danube regions. Countries in the latter group were swept by a wave of land reform immediately following the World War which contemplated a supplanting of the old aristocratic estate system by one of small peasant proprietorship. In this the purpose was primarily social and political rather than economic, and led to a falling off in cereal exports, owing to a decline in efficiency of production and to more liberal consumption by the peasants. These countries have found that the decrease in wheat exports has resulted in an unfavorable trade balance and they are now taking steps to increase the efficiency of agriculture.

Rumania and Czechoslovakia have carried out the program of the division of large estates most consistently and effectively, and they have done much to organize the farmers and to educate them in the modern methods of agriculture. Bulgaria and Yugoslavia had less of a problem of land reform, but have both been active in the program of agricultural education and technical improvement. In several of these countries, notably Czechoslovakia and Hungary where industrial development is roughly equivalent to interest in agriculture, close attention is being given to agriculture in a balanced national policy.

Outside of Europe we find emphasis on agricultural production most pronounced in the lands of comparatively recent settlement whose sparse population, limited capital and meager industrial raw materials predispose them toward the business of supplying agricultural raw materials to the great industrial centers. Argentina presents an interesting illustration of a country in which the present development and future outlook seem definitely to be cast in agricultural terms and yet in which no very vigorous or daring program of assistance to the farmer and stimulus to the agricultural industry has been worked out. Several of the British dominions, on the other hand, have shown a tendency, particularly during and after the World War, to build up agricultural efficiency and accelerate the rate of agricultural exploitation through liberal land systems, transportation aids, effective credit institutions and practical systems of popular education. Such schemes of government aid of export marketing experiments designed to increase the efficiency of the handling process and improve the commercial position of the producers as a group are still being developed in Canada, Australia, New Zealand and South Africa. In several cases these coun-

tries have espoused even more radical measures to strengthen the position of their agricultural producers in the world market. These include, in addition to the fostering of wheat pools and other centralized cooperative organizations, experimental legislation in the field of compulsory cooperation and the establishment of supervisory boards exercising considerable regulatory power over given branches of agricultural industry. The prairie provinces of Canada, for instance, have perfected a voluntary cooperative wheat pool possessed of the chief advantages of the war time government grain monopoly but at the same time working out experimentally the possibilities of a large scale effective organization of private agriculture. Canada is an outstanding example of a country with provincial governments not only distinctly agrarian in origin and outlook, but so organized and with such a party alignment as to make the weight of the agrarian interest felt in the field of Dominion government.

Agricultural policy in the United States has varied considerably in emphasis. Throughout the first hundred years of our national history we were so dominantly an agricultural country that any effort toward national progress almost of necessity included a policy of support and stimulation for agrarian interests. In the pre-Civil War period the farming industry was helped by a liberal land policy, rather aggressive governmental aid to transportation development and freedom of immigration. There were also some bits of tariff protection and a moderate effort along educational lines. All this tended simply to hasten the country's natural growth in the rich soil of its agricultural resources. Our economic system was based on maximum freedom of enterprise, and farmers were left, broadly speaking, to work out their own destinies in a land of pioneer opportunity.

After the Civil War the Homestead Act and subsequent land distributing measures, along with the liberal aid to railroad building, accelerated the growth of our agricultural domain. At the same time the establishment and expansion of departments of agriculture, agricultural colleges and agricultural experiment stations added to previous educational efforts to increase the nation's agricultural production. Obviously all this did not constitute a policy of encouragement of agriculture as against or superior to a desire for the nation's industrial growth. The improvement of transportation facilities ministered to the growth of industry as well as

of agriculture, and the flood of cheap food and raw materials resulting from the growth of our farming industry did much to facilitate the establishment and progress of manufacturers. The first point at which any major clash of interests was settled by action definitely favorable to the farmer came with the passing of the Granger railroad laws and the establishment of the Interstate Commerce Commission in 1887.

The severe agricultural depression of the middle nineties brought out sharply the fiscal aspect of the farmer's problem. With an almost universal desire for individual ownership, farmers in America have been habitually in the debtor class. As such they would have been inevitably opposed to any financial policy which would lower the general price level and they have insisted on liberal credit extension and low interest rates. Their attitude has been strikingly expressed in the greenback movement following the Civil War, in the free-silver controversy of the nineties and in the bitter opposition to such deflationist practises as have followed the World War. In all three of these struggles agrarianism has been upon the losing side, and the financial policies which have triumphed have been those of "sound money" as against inflation for the purpose of lightening the debtor's load. With reference to credit, however, the national policy has tended toward continual liberalization and the building up of credit machinery adapted to the farmer's special needs. The high interest rates which farmers have had to pay, and against which they have protested continually since the days of early pioneer settlement, have been due in part to the natural handicap of sections remote from the centers of capital supply, and of unorganized borrowers whose risk factor was high. These disadvantages have been lessened with the growth of the country and the perfecting of general credit machinery. At the same time, the farmer has made his needs better known. A change in policy emerged gradually in the discussion of money and banking reform that followed the free silver agitation and led up to the passage of the Federal Reserve Act. With the passage of the Federal Farm Loan Act in 1915, and of the Intermediate Credit Act in 1923, the policy of adaptation of the credit machinery to the farmers' needs received definite expression.

A further development of American agricultural policy represents a response to the long reiterated complaints against marketing conditions for agricultural produce. Numerous acts passed by state and federal governments during

the last four or five decades, but especially since about 1913, have provided for grading, standardization, inspection and price reporting in great variety. Since the agricultural depression of 1920 there has been renewed demand for governmental intervention in the price system to eliminate the risks of price fluctuation due to manipulation of the market, seasonal inequalities of supply or even the longer secular movements. This program has been stubbornly opposed thus far, but the legislation of the special session of Congress convened in April, 1929, seems to recognize the propriety of government action looking to the stabilization of markets against manipulative influences and against the results of peculiar climatic conditions. It remains to be seen whether the practical interpretation of this latter doctrine will give a maximum or minimum of governmental assistance, but it seems clear that our policy still excludes the idea of the stabilization of any agricultural industry over a period of years in a position which it could not maintain under such conditions of competition as accompany our system of protective tariff.

AGRICULTURAL SOCIETIES for mutual aid and for study of technical problems existed in the Roman Empire and could be found here and there in Europe during the Middle Ages. The agricultural revolution, which changed farm practises, and the development of a philosophy glorifying agriculture and rural life constituted, however, the twofold foundation on which modern technical or scientific agricultural societies were first built. The latter basis was most conspicuous in France, the former in Great Britain. In the middle eighteenth century agricultural societies were formed in Paris, Tours and other cities under the influence of the physiocratic philosophy. In Scotland an agricultural society was established as early as 1723, followed by one in Ireland in 1731, one in the west of England in 1777, and one in London in 1793. The Royal Agricultural Society of Denmark, composed of large estate owners, was founded in 1769, while the first of the Danish educational agricultural societies came into being in 1810. All these organizations, with the exception of the last, were composed of extensive landholders or urban professional men rather than tillers of the soil. Emphasis on practical farming and the everyday problems of rural life developed early in Denmark because of the division of the land into farms suitable for family occupancy and cultivation at the close of the eighteenth century.

The American agricultural societies were founded largely upon the English models. The first such organization—which was not, however, confined to agricultural interests—appears to have been founded on Long Island in 1763, but nothing is known of its activities. The earliest society to make a definite impression was the Philadelphia Society for Promoting Agriculture, formed in 1785. George Washington, Benjamin Franklin and Timothy Pickering were members. In the same year the South Carolina State Agricultural Society was founded. Within the next few years societies were established in various places in the Atlantic coast states, both north and south. The Columbian Agricultural Society, which had national aspirations, was founded at Georgetown, D. C., in 1809. It never achieved its high ambitions. The first Canadian agricultural society was founded in 1798. Inspiration for these societies came both from the desire to improve agriculture by crop rotation, as had been done in England and on the continent, and from the view that rural

life made for private virtue and national greatness. The membership of the societies was made up chiefly of lawyers, merchants, physicians, clergymen and politicians, with a mixture of large landholders and a very few practical farmers. The organizations published scientific papers on agriculture, held meetings at which scientific topics were discussed, and offered prizes for agricultural discoveries. These societies were generally unsuccessful in reaching the working farmers. An exception among these organizations was the Kennebec Society, founded in Maine in 1787 by actual farmers. Its activities, however, were confined chiefly to meetings at which papers were read and discussed.

In 1810 Elkanah Watson, a wealthy retired business man, who had seen the ineffectiveness of the older societies, enlisted the cooperation of his rural neighbors in holding a livestock fair in Pittsfield, Massachusetts. As a result of this the Berkshire Agricultural Society was founded. This, while not strictly the first county society in the United States, really inaugurated the county agricultural society movement. Watson himself was an indefatigable propagandist, and societies were established in practically all the counties of New York and New England, as far south as North Carolina, and as far west as Illinois. State aid had been extended to some of the older state societies and it was inaugurated by New Hampshire in 1817 for the county organizations. Several other states followed suit. The principal achievements of the early county societies, aside from establishing a measure of community interest among farmers, were the cattle shows and fairs with their educational exhibits, their competitions and their social features. The societies increased rapidly until 1825, then declined up to 1835, following which there was somewhat of a revival of interest in them. The state societies continued to exist, gradually adding an increasing proportion of practical farmers. These societies promoted the establishment of boards of agriculture and agricultural schools, and in some cases urged, and succeeded in restoring, the old system of bounties for certain crops. The bounty scheme was unsuccessful. The present state boards and departments of agriculture owe their existence, however, largely to the agricultural societies. These organizations also were in part responsible for the increased interest in agriculture in the middle of the nineteenth century, which eventually led to the

establishment of the Land Grant colleges and the agricultural experiment stations.

In 1852 twelve state agricultural societies formed the United States Agricultural Society, which it was intended should coordinate the work of county as well as state organizations. Its membership included not only farmers but men prominent in politics. It met annually and held national exhibitions and field trials. It exerted powerful influence in behalf of the establishment of the Department of Agriculture (1862). The United States Agricultural Society existed until 1881.

Later the economic problems which had been created by the Civil War and not emphasized by the older societies were dominant in the minds of farmers, who turned in great numbers to the Grange and similar organizations. Subsequently, with the increase in scientific knowledge and the growth of specialized farming, there occurred a differentiation in technical agricultural societies on the basis of the crops grown or livestock raised. Horticulture had always been regarded as somewhat distinct from agriculture in general, and horticultural societies had existed since 1829. In some states they had succeeded in establishing boards of horticulture comparable to the boards of agriculture. In the last quarter of the nineteenth century growing interest in pure bred livestock led to the organization of numerous breed associations, to promote the improvement of the respective breeds and public interest in them. Registries of pure bred stock were started by these societies. The breed organizations now number about two hundred, representing every important breed of dairy cattle, beef cattle, horses, sheep, goats, swine and poultry raised in the United States. Societies were started for specialists in various field crops, vegetables, fruits, nuts and other products. There are also various technical organizations, such as the American Society of Agronomy, composed chiefly of college professors and scientists. Different from any of the societies heretofore mentioned and resembling some of the agricultural clubs in European cities is the Saddle and Sirloin Club, with headquarters in Chicago. Membership, which is by invitation, is intended for leaders in all branches of the livestock industry. It has held contests and employed other methods of stimulating the interest of students in agricultural colleges.

State agricultural societies still exist, but are

less influential than in early days. County agricultural societies have largely disappeared, their places having been taken by county farm bureaus and by local branches of the Grange, the Farmers Union and similar organizations. Local farmers' clubs have come into existence in considerable numbers in the last quarter of a century. Some of them discuss scientific problems, but for the most part their emphasis is upon community improvement.

In most countries, including the United States, the technical or scientific agricultural societies have maintained a traditional isolation, neither joining with other societies of the same type nor federating with economic, political or other organizations of farmers. Close and workable union is found only in Denmark. There all the farmers' societies, of whatever nature, center in the Agricultural Council of Denmark (Landbrugraadet). This is made up of representatives of the Royal Agricultural Society, composed principally of owners of large estates; the educational or technical agricultural societies, numbering one hundred and thirty-seven, which are local and comprise about 90 percent of the farmers; and the federated commodity cooperative associations, to which approximately 85 percent of the farmers belong. This system has worked with marked success in correlating all the agricultural and rural interests of the country. In most European countries the cooperative associations, through which farmers both buy and sell, have outstripped the technical societies in influence.

I. PRIMITIVE AGRICULTURE. Just how and where mankind fell into the custom of planting and cultivating may always remain a matter for speculation. Among the proposed theories of its origin are those which assume that agriculture began in tropical areas, where it is supposed plants can be grown with minimum effort, and reached its full development when tribes accustomed to this mode of life migrated to drier lands, where greater difficulties were encountered. Another set of theories reverses the process, assuming that agriculture began in arid places where life was hard and vegetation sparse and developed in the effort to protect and to conserve the wild plants. Yet none of these theories need be taken seriously until the data essential to such conclusions are available. However, it appears that the most ancient cultures known to have practised agriculture tended to center in semi-arid areas. This is conspicuous not only in the Old World, as in Egypt and the valley of the Euphrates, but also in the Americas where the most intense development of agriculture occurred in dry sections of Mexico and the South American Andes. While these observed tendencies have been cited as corroborative evidence for the arid land origin theories, the general opinion at present is that the location of these old civilizations in such dry areas was due not to environment alone but to a complex of causes, and that the advanced state of agriculture therein was a result rather than a cause. It may turn out that agriculture is even less arduous in semi-arid lands, since there are many factors in the complex procedure of food production; yet even could we prove that agriculture first became effective in semi-arid lands, it would not necessarily follow that the initial step was in such an environment. We may, however, approach the problem in another way.

A survey of primitive life shows that everywhere man makes use of vegetable food. Except

in arctic and near arctic areas, there are relatively few environmental restrictions on the quantity of such food used, although the kind chosen may be so governed. The cultivated food plants of primitive man fall into two main classes, tubers and grains. The great domestic grains of the world are wheat, rye, barley, oats, maize, rice and millet. Of these wheat, maize and rice stand in the foreground. History and archaeology have so far brought to light no great civilization not largely dependent upon one of these three grains. Non-agricultural peoples make more or less use of cereal substitutes, usually wild grains. These may be the seeds of various grasses, for example wild rice in the Great Lakes region of North America. The extended use of the acorn, especially in aboriginal California, where acorn meal was a staple, may be set down as another example of a cereal substitute, as also is the manioc of South America, which is made into a kind of bread. Returning to the question of origins, the natural assumption is that agriculture came as a shift from wild species to domesticated forms; these transitions may have occurred quite independently of each other. However, since the transition must have been from wild to domestic plants, the place of origin for such domestication may be approximated by locating the parental wild species and its habitat. Such lines of inquiry are both historical and botanical, first to locate the wild species and then to trace the diffusion of the domesticated forms. However, the botanical problem has proved more difficult than might be supposed, because the domestication process produces so many modifications in structure that the identification of the wild plant is uncertain. In the case of maize, for example, there is still some doubt as to the wild ancestral form, but the prevailing opinion is that it was derived from teosinte, a wild grain growing in parts of Mexico. Wheat has been traced to certain wild grains in western Asia and its domestication is

now believed to have occurred in Anatolia under primitive conditions.

Once a plant is domesticated, its cultivation may readily spread from people to people, in so far as climatic conditions permit. In recent discussions of the subject diffusion of agricultural practises and migrations of agricultural peoples are looked upon as the important factors in the spread of domesticated food plants. Should a tribe shift from a region where wild grain abounds, it is conceivable that effort might be made to transplant the grain to the new habitat and thus initiate an agricultural practise. From what is known of culture in general, it seems more than likely that agriculture would develop out of group contact and changing situations.

Furthermore there is good reason to believe that the practise of agriculture increases population and that an expanding tribe or village would from time to time throw off a colony seeking new lands. This would spread plants and their cultivation over large areas. But migration is not necessary to the spread of cultivated plants; one tribe may learn from another. Moreover in a large agricultural area a new and better food plant could spread with great rapidity. The geographical distribution of maize in the New World, and of wheat and rice in the Old, suggests such diffusion.

It should be noted, however, that the cultivation of food plants does not stand alone in the culture of a tribe, but is connected with many other culture traits. For example, the mechanization of agriculture is an integral part of primitive mechanics. Among other devices the digging stick, the hoe, the wheel and the plow are the most conspicuous. The substitution of animal for man power in the culture of a people has also a direct influence upon agriculture. It was of course this substitution that made plow culture what it is. A plow drawn by oxen appears in Egypt at an early date and seems to have been even then widely diffused in the Old World. The contrasting type of agriculture which did not use draft animals and the plow is best seen in the New World, where the digging stick and the hoe were the only tools. It is also observable that maize and manioc are adapted to hoe culture, whereas the great cereals of the Old World are still grasses, to be sown rather than hoed. Maize in the wild state seems to have been a grass also, but its cultivation was by the hoe; or, to put the matter differently, the modification of the wild plant was in the direction of adaptation to hoe

culture. The other parts of the world where hoe culture prevailed at the period of modern discovery were central and south Africa and the islands of the Pacific. It is significant that in the Old World the diffusion of plow culture and the cereals, wheat, rice, etc., carried along the ox and possibly the horse. In some parts of Africa although cattle were known the plow was not used. Moreover the use of the cart seems chiefly associated with plow culture. It has been said that the greatness of Old World civilization was due to wheat, and while there is much to be said in support of this, the importance of other associated facts should be noted; it is rather in the combination of wheat, plow, cart and ox that the basis of these old civilizations is to be sought. Whether all these inventions originated contemporaneously and among the same people is not known, but they appear together in early Egyptian and Babylonian cultures and from that time on function in the culture of every Old World power.

That the wheel and plow are early inventions is clear, because their origins can be traced far back into prehistoric time. Most writers follow Tylor in suspecting the plow to have been derived from the hoe and the wheel from a rolling log, but again there are few relevant archaeological and historical facts. Nor can more be said respecting irrigation, a method known to be archaeologically ancient and possibly the first important step in the development of agriculture in semi-arid lands. The effectiveness of agriculture everywhere depends upon human control and adjustment to the factors involved, and given a semi-tropic climate and dry lands as constants and a water supply easily controlled by man, effective agriculture is easy. Finally even the most backward agricultural tribes knew that selection of seed is necessary to improve and conserve domesticated plants, and understood the value of fertilizers. The most that we can say, then, is that agriculture, domestication of draft animals, food plants, the hoe, the plow and the art of irrigation, all emerged on an ancient primitive horizon.

An important social aspect of early agriculture is the concerted effort needed to protect the crop. A small plot of growing plants in a forest clearing or even in a reclaimed semi-arid locality would stand as a constant lure to the wild life of the region. So the growing crop must be guarded not only by day but also by night. This can best be accomplished by arranging the individual plots cultivated in series near the

camp or village, and organizing a system of watchers in relays.

Another important social implication of primitive agriculture lies in the need for instruction in technique. Among the important procedures are the selection of the seed and the choosing of the time for planting and for harvesting. This function may be served in part by the planting and harvest ceremonies so characteristic of all but ultra-modern agriculturists. Naturally these are complex procedures involving the religious life of the tribe, but often formulae for planting, etc., are interwoven with these rituals. The keepers of these rituals usually select the seed and announce the time for planting. In other words the community is led by experts. Primitive agriculture as it has been observed is a cooperative effort in which the community as a whole participates. Thus the essential part which agriculture has played in the growth of culture is attributable not merely to the fact that food is thereby provided but also to the fact that humanity itself has been more closely knit and disciplined by the procedures involved.

II. AGRICULTURE IN ANTIQUITY AND THE MIDDLE AGES. The earliest historical information, as distinct from anthropological evidence, that we have on the subject of agriculture comes from Egypt and Babylonia. These two countries were areas of civilization along the banks of rivers. It was the Nile that made agriculture possible and this in turn was the foundation of Egyptian civilization. Wild barley grew in the district, and the periodic flood of the river invited its cultivation. Wheat (or spelt) was probably almost as important. Once a year the Nile overflowed its banks, covering the land for about six weeks and depositing a fine fertilizing silt. Then the waters flowed back again in October, leaving the land moist throughout the winter with but little evaporation. With this one dose of water, grain could be cultivated with great success. Only near the mouth of the Nile was water stored for further use or for second crops. Out of this crop situation came an agricultural state with a presiding agricultural deity, an agricultural calendar and a technique of cultivation that was relatively high. Nature had laid the foundations so successfully that in mediaeval and early modern times even misrule, mismanagement, warfare and general disorgani-

zation did not wholly destroy the system.

The Babylonian civilization was also built upon irrigated agriculture. The Tigris and the Euphrates, however, were not like the gentle, dependable Nile. Their waters came with a rush and had to be pent up for future use, since the flood occurred in May. Out of the elaborately constructed basins the water was then allowed to flow by degrees to satisfy the land otherwise baked by the midsummer sun. Unfortunately the deposits of the flood were neither so fine in quality nor so wholesome in chemical composition as those of the Nile. But parts of the land were of tremendous fertility and needed only water. Here, as in Egypt, a crude plow drawn by oxen was used and the same kinds of grains were planted. Although there are fewer sources for a study of Babylonian agriculture than of Egyptian, still there are pictorial representations and inscriptions of great value. The Code of Hammurabi shows the dominance of land cultivation, while an Akkadian tablet of precepts provides us with details of the technique of agriculture. The land not only had to be irrigated but also manured.

Among the Greek states a non-irrigated system of agriculture prevailed. Of this we get glimpses from Homer and more detailed information from Hesiod, Theophrastus (*Plants*, bk. viii) and Xenophon. It would seem that a fallow system of extensive agriculture was followed in favorable locations by a somewhat intensive system of cultivation, in which grapes, olives and figs played a dominant part. Greek methods spread to third century Egypt, probably to Carthage and certainly to Italy.

We know not a few details about the methods of carrying on agriculture in the village of Philadelphia, in the Fayum, Egypt, settled largely by Greeks in the third century B.C. (see Rostovtzeff's *Large Estate in Egypt*). Originally a sandy stretch, it was reclaimed by irrigation until it could produce two crops a year—one by the flood of the Nile, the other by artificial elevation of the water. We know that some of the land was left fallow, possibly to eliminate weeds. Oil plants, hay and wheat were the chief field crops. Grapes were grown and wine manufactured. Beer and honey were produced for sale. Melons, pumpkins, onions and garlic were the chief vegetables. Cattle, horses, donkeys, sheep, goats and fowl were raised. A surplus of cheese and wool was available for sale.

In general it may be said that with the cessation of nomadic agriculture, that is, when men

settled down in permanent villages, field work was combined with animal husbandry and the plow was hitched to some beast of burden. The land was kept clean, and moisture was conserved by fallowing a large part of the tilled area. At a later stage a leguminous plant was used in rotation with fallow and a cereal crop. Such a plant adds to the nitrogen content of the soil and, when plowed into the soil, improves the tilth. In all probability Greece, many parts of North Africa and much of Italy at least approached or entered this last stage.

The early Roman state was built upon agriculture, as was the Egyptian state. But whereas in Egypt the agriculture was based on irrigation, in the Roman lands irrigation was either not used or but slightly relied upon. Until about 200 B.C. the estates were typically small and the cultivators were freemen. In parts, notably in Latium, there was soil exhaustion. Everywhere there was the drainage of man power for the numerous wars. From about 200 B.C. to the time of Christ large slave plantations became the typical agricultural unit. This new development occurred as Roman conquests brought in more and more slaves. Some of the plantations grew wheat as in Sicily and North Africa; others, for example, in the eastern part of Italy, were devoted to animal husbandry; and still others, smaller in size, specialized in olives and grapes. The third period, from the time of Christ to about 200 A.D., saw the large estate with free tenants take the place of the slave plantation. It seems to have arisen through the diminution in the supply of slaves and the recognition of the inefficiency of slave labor. Apparently there was but little change in technical processes. From about 200 to 400 A.D. the free tenants lost their free status, and from about 400 to 800 A.D. these unfree tenants were forced to work on the lord's home farm. This was the manor which arose as a relatively self-sufficing organization at the very time the Roman empire was disintegrating.

For a study of the technique of Roman agriculture we are possessed of invaluable contemporary treatises. And it is a significant fact that almost the first literary efforts of the Romans went into the composition of such treatises. The earliest was written by Cato (234-149 B.C.). What he owed to the Greeks and to Mago, the Carthaginian, we shall probably never know. But most of all he derived his knowledge from experience. He urged the sale of the greatest amount of produce and the

purchase of the smallest amount of goods. Olive oil, wine, cattle, sheep and worthless or outworn slaves were to be sold at the highest price. Varro (116-27 B.C.) wrote a much fuller and a better organized treatise. Tillage, animal husbandry and the raising of fowl, rabbits, bees and fish are all considered. To him it appeared that Italian agriculture was a success but not an unqualified success. Columella, Palladius and other writers followed, but they are of less importance.

The Romans grew barley and wheat but probably neither rye nor oats until late in their history. They used milk but not butter, cheese or beef, at least not to any great extent. Fowl and rabbits were delicacies. Grapes and olives were of increasing importance in the republican era.

The poor results which were obtained by Roman agriculture are probably to be assigned to the use of slaves, negligence in applying manure, clumsy tools, neglect of seed selection and bad rotations. All three forms of agriculture were practised, that is, natural husbandry (in spots), the fallow system and legume rotation. The emphasis which is put upon legumes by Varro, Pliny and Columella is significant. Virgil in his *Georgics* describes a legume rotation made up of legume, grain and fallow. He advocated the burning of the stubble on barren soils, cross plowing and seed selection.

When the Roman Empire disintegrated, barbarian peoples rose upon the ruins. The Celts of southern Gaul had an advanced system of agriculture, while their fellows in Britain were more primitive. In Britain cattle raising seemed to have predominated in Caesar's time, and by about 360 A.D. grain growing was sufficiently developed to provide a surplus which was occasionally sent to the Rhine district. It is difficult to determine the nature of the purely Celtic plow. There is much uncertain conjecture as to the practices of the Celts in plowing or digging their fields. It is reasonably clear that their cultivated plots were rather small and tolerably square. For the study of this subject Captain O. G. S. Crawford has recently opened up a new method through aerial photography. He began his work in the chalk downs of Hampshire after the Great War. The villages of the Celts were so often elongated, strung out along a street, that Meitzen and others have considered this a racial or national characteristic.

Whether the village of the barbarian peoples, the Celts, Teutons and Slavs, was originally free or servile, public or private, has long been

a matter of dispute. The issue came to be bound up with that general conflict between the Teutonists and the Romanists which in modified form still continues. But we have now reached a somewhat middle position that seems to be in keeping with the evidence. This position is that, while the normal development was from a public village of free men owning a share in the land and rights of pasture and cutting wood, there was also a very different development out of the large private estate of slaves possessed by military leaders. These two radically different institutions, the former abundantly illustrated in Teutonic lands, the latter in Roman provinces, both resulted in the manor. While the free village had only to add a home farm, the private state, starting with the home farm, had only to add tenants cultivating lands of their own.

Under the leadership of Meitzen it has been thought that agricultural communities took form according to racial or nationalistic tendencies—that the Celtic village was a street settlement, the Teutonic a central irregular cluster of buildings with lands on all sides, and the Slavic a more regular and somewhat roundish array of buildings, access to which was through a single road that ran into the village as a blind lane. There is evidence for these views, but the tendency of recent scholarship is to emphasize local physical characteristics.

Just as the manor developed in the period up to 800 A.D. in Italy and the Roman provinces, so following that date it arose in the northern and western part of Europe. By the thirteenth century it was at its height, and by 1350–1500 it was declining rapidly in such parts as England and northern France. In Germany and Russia decline came much later.

In a general way the technical agricultural development was pretty much the same in northern and western Europe as it had been in Mediterranean lands. After natural husbandry came a fallow system which in places rose to the height of a legume rotation. The technique which was found most commonly in the period 800–1300 was the fallow system. The village area was divided into arable, pasture, meadow, woodland and waste. The arable was cultivated with a twofold or threefold rotation called the two-field and three-field systems. Of this latter system we have most information, partly because it was apparently most prevalent and partly because it lasted in many lands down to the nineteenth century.

In the three-field system there was one field left fallow, one devoted to a winter grain (such as wheat or winter barley) and one to a spring grain (such as barley or oats). Small amounts of beans, peas and vetches were also planted with the spring grain. And there were combinations of cereals such as mancorn or mistlin (wheat and rye, or wheat and winter barley), drage (barley and oats), and brotcorn (sometimes barley, peas and vetches). Since the different grains did not ripen at the same time, there were objections to such combinations.

Weeding was practised, as was manuring. In the thirteenth and fourteenth centuries about two bushels of wheat were sown to the acre and the net yield was about six to eight bushels on average soil. Plowing was not deep nor was the furrow turned right over. Seed was not selected, although it was often brought, at least by manorial lords, from other manors. The field operations were subject to the control of the manorial tenants under the guidance of the lord's officials, meeting together in the manorial court.

The two or three fields were big open stretches; hence the term open field system which is applied to the cultivation. Each field was divided into small sections called shots or furlongs which were in turn made up of small ribbon-like strips of one quarter or one half acre in size. Commonly these strips were not straight but like an "s" somewhat drawn out, a condition said to be due to the necessities of turning a plow team. The shots or furlongs probably represented a section which had been brought under cultivation at one time, each of the tenants, and sometimes the lord, having one or two strips in it. Indeed the shots were often the most important units of the land, since they bore an individuality and had a name.

The lord had a home farm of varying size, part of it in open fields and part of it often set aside, sometimes by enclosures. To him belonged special control over the pastures, which ordinarily were common, and over the woodland, which supplied timber, firewood and mast for pigs. To some scholars the distinguishing feature of the system of cultivation is the permanent separation of arable, pasture and meadow. A piece of land once set aside for one purpose was likely to be kept to one use. However, after the crops had been harvested, the livestock were allowed to feed on the stubble, either watched or fenced in by improvised hurdles. And after the hay had been cut the

meadow was turned over to pasture—until the next year.

In animal husbandry there was little selection of sires and no segregation. Promiscuity and community of diseases resulted. The murrain (a general term) and pox were terrible scourges; copperas, verdigris, quicksilver and oil were used to counteract them, and also pitch or tar. Sheep's milk and cow's milk were made into cheese. Butter was less used in the Middle Ages than now. Pork was more highly prized than mutton or beef. Sheep were raised for wool, and cattle for draft purposes and for milking.

Agricultural equipment was very restricted in the Middle Ages. There were the spade and mattock, the plow and the flail. The well made plow had a wooden beam, iron share, iron colter, handles, wheels or foot irons and a yoke. It was drawn ordinarily by oxen, from two to eight in number. The cart was a wooden affair equipped with harness and a ladder, all of purely local manufacture.

Labor on the manor was normally unfree and ineffective. The laborers, that is, tenants of the manor, often had to be amerced for bad work and were always watched to keep them from stealing. For their labor they received allowances of grain, meal, pigs, lambs, cheese and ale. These helped to eke out a livelihood, which was none too good, from their own holdings of from five to thirty acres. Without their pasture rights they would have been pretty close to the line of mere subsistence. As it was, if they added some home manufacturing of cloth or wooden utensils for sale, they were in a fair position.

Improvements were attempted here and there by manorial lords. Walter of Henley's *Husbandry* is clear evidence of intelligent management. But the dead weight of an unintelligent peasantry made improvement difficult. The probable shift from a two to a three-field system was an improvement. With less plowing there was more land for grain. There is some local evidence of a slight increase in yield per acre. The addition of a legume to the round of fallow, winter grain and spring grain was an improvement which, however, was neither common nor persisted in. Some exhaustion occurred locally, but there seems to be no general evidence of soil depletion or fouling.

The advent of a manorial system imposed upon free villages may have forced the villagers to make better use of their time, since they had to work for the lord as well as for themselves. In some instances it set up a better ex-

ample of cultivation, and it also led to restraint in use of both pastures and woodland. The monasteries, priors and bishops were probably the most enlightened lords, but after about 1350 in western Europe they probably contributed much less than formerly, and they are thought by some to have become more conservative than lay lords. Towns took their places as the dominant influence of the day. Peasants escaped to the towns to become free and engage in varied occupations. Those who remained could the better bargain with their lords, at least for a period.

III. THE AGRICULTURAL REVOLUTION IN ENGLAND. Village farms are peculiarly adapted to groups of settlers living in a thinly populated country, hemmed in by forests and constantly exposed to attack. In England, as in the rest of Europe, the characteristic form of agricultural organization was that of the manorial system, essentially groups of village farms. Isolated from one another, each community was necessarily self-sufficing, and for mutual protection gathered in clusters of houses, surrounded by meadows, tillage and pasture. Common arable cultivation safeguarded them against extremes of bad farming and secured continuity of practice. Common grazing rights maintained the livestock, which provided plow teams, manure, meat, milk and clothing. Common rights in adjacent woodlands supplied timber for building, fencing, implements, utensils and firing. Farming was for subsistence, not for profit. The system flourished in the conditions which gave it birth. As England became populous and industrial, changes were inevitable. Markets arose; means of communication improved. Cultivation for local consumption ceased to be the necessary basis of agriculture. Differentiation of employment and specialization of production developed. Individual tenancies multiplied. Continuous grain growing on the area occupied by each community, however unsuitable the climate or soil, was necessitated by farming for subsistence. But agriculture gained when the uniformity and rigidity of the old system were supplemented by the greater diversity and elasticity of the new.

The movement toward individual use of land began long before improved methods and resources demanded the removal of village farms

as obstacles to productivity. Many causes hastened its advance. Under Edward I manorial organizations reached their highest administrative efficiency and the servile status of villeins its most precise legal definition. Yet both were changing their character. Land became a source of profit rather than of power, and money was more necessary than retainers. Hired labor was supplanting forced labor on the lord's demesne and rents or wages in cash were displacing personal services as the nexus of new relations between landlord and tenant or employer and employed. Feudalism retained the splendor of its superstructure, but its foundations were decaying.

Individual tenancies were created by enclosures, which began when manorial lords withdrew their demesnes from village farms, fenced them in compact blocks and cultivated them by the services of their tenants or, when these services were commuted into cash, by hired wage labor. Fresh land, brought into cultivation from woodlands, wastes and commons, was generally added to demesnes or let in separate holdings to individuals. By common and statute law such lands belonged to manorial lords, in whose grant or sufferance, in legal theory, originated all commonable rights enjoyed by tenants of arable holdings. If these obligations were satisfied, they could enclose the surplus. Nor did enclosures of this type necessarily cripple village farms. Sometimes they even helped to meet new needs. Agrarian partners agreed to enclose closes from tillage, convert them into pasture and regulate their use. Such treatment only palliated widespread difficulties. Continuously cropped for grain, insufficiently manured, inadequately relieved by weed infested fallows, their arable was wearing out. The only remedy was to lay exhausted tillage to grass and plow corresponding areas of pasture. That cure was unattainable by village partners. Small holdings of fifteen arable acres ceased to yield livings; but the services attached to their tenure remained. This decreasing fertility aggravated the effects of the Black Death and other disturbances of the fourteenth and fifteenth centuries.

Traveling eastward over Europe the Black Death reached England in August, 1348, and destroyed nearly half the population. Wide tracts of land lay uncultivated without tenants or laborers. Although the government endeavored to compel all who practised husbandry to work on the land at the wages of 1346, relations

of supply and demand proved stronger than legislation. The Statute of Labourers (1350-51), frequently reenacted, failed to prevent the natural consequences of the Black Death. As an agricultural organization the manor was shattered. Individual holdings were multiplied and enlarged; the emancipation of serfs proceeded rapidly. Unable from scarcity or cost of labor to farm their demesnes, landowners leased them in separate tenancies. On village farms substantial partners took up holdings vacated by occupants who had died, fled or purchased licenses to be exempted from occupying lands. Many bondsmen escaped; many were manumitted as offerings to avert God's anger; many made their occupation of land conditional on personal freedom. Even the statute assisted emancipation. By recognizing the prior claim, but not the exclusive title, of manorial lords to the services of bondsmen, it conceded some liberty of movement. So long as the law sanctioned personal servitude, it menaced a mass of the rural population. In the Peasant Revolt of 1381 they demanded the abolition of villeinage and attempted to destroy manorial court rolls, because they registered their status as well as their titles. Though the law still threatened their liberties, the servile tenure was fast losing its practical meaning, mainly because feudal landlords abandoned patriarchal farming for rent receiving.

Village farms stood outside modern developments. Relics of primitive society, their framework remained for centuries unaltered. But their subsistence farming was becoming obsolete. From the Tudors onward commercialism permeated national life. It invaded agriculture, which reorganized itself on a money basis. Land passed to new landlords who required profits. An ominous growth of land speculators appeared. Separate tenancies, large enough to encourage enterprise, had proved their value. Occupying owners and capitalist farmers increased their holdings by absorbing those of smaller men. A general movement, following commercial lines, threatened village farms and small independent occupiers. Cloth manufacturers created a demand for wool and made sheep farming more profitable than corn growing; hence large tracts of fenced pasture were needed. Small occupiers were the easiest and chief victims. Tenants at will were evicted; leaseholders or copyholders were bought out or compelled by exorbitant rents or fines to surrender tenancies.

Village farmers, however, were better protected. Mutual rights of common rendered it difficult to dissolve partnerships without agreement. But if coercion or persuasion secured consent, arable fields were laid to grass and thrown into sheep runs. Consolidations of small separate tenancies assisted enclosures for pastoral farming to depopulate rural districts and replace hamlets by solitary shepherds. Alarmed by the "decay of people" and fearing scarcity of bread, Tudor governments passed numerous acts forbidding conversion of tillage to pasture, ordering newly laid grass to be plowed, directing removal of enclosures and rebuilding of decayed houses, limiting the farms or flocks which one man could hold, imposing penalties for disobedience. Legislation was comparatively ineffective, partly through evasion or lax administration, partly from the futility of forcing men to grow grain on exhausted arable. By 1560 the enclosing and engrossing movement had spent its revolutionary violence.

A transitional period, the sixteenth century depressed the lower and raised the middle classes. It severed small occupiers from the soil, leaving them dependent on wages. But yeomen prospered on enlarged holdings and leaseholders and copyholders secured tenures for life or lives. Agriculture progressed slowly. Enclosures of separate tenancies in compact blocks prepared for advance; except as restoratives, conversions of tillage to pasture were retrogressive. Yet throughout the sixteenth and seventeenth centuries writers advocated changes which, under George III, revolutionized British farming. The first original work on agriculture printed in English was *The Boke of Husbandrye* (1523) by John Fitzherbert. Writing from forty years' experience Fitzherbert urged the advantages of farms in individual occupation divided into separate enclosures, and advocated mixed husbandry in which stock and corn assisted each other. Thomas Tusser followed with *Hundreth goode pointes of Husbandrie* (1557), expanded into *Five hundreth Points of Good Husbandry* (1573). Like Fitzherbert he suggested no new resources, and neither had traveled outside England. Barnabe Googe was both translator and traveler. His *Four Bookes of Husbandrie* (1577), mainly translated from Heresbach's Latin work, urged the introduction from the Low Countries of turnips and artificial grasses. Other writers followed Googe, notably Sir Richard Weston, whose *Discours of Husbandrie used in Brabant and Flanders* (1645), pirated by Hartlib, was

printed in 1651 as *Samuel Hartlib his Legacie*. The book contains the "Large Letter" of Robert Child. Book farmers suggested many improvements besides turnips and clover. Thus John Forster (1664) urged potatoes as field crops. Sir Hugh Plat, in his *Jewell House of Art and Nature* (1594), Walter Blith and Child collected imposing lists of manurial substances. Plat recommended putrifying pilchards and Child mentions that New England farmers used on the land a fresh-water fish called "the Ale-wife because of its great belly." Drainage was sensibly discussed by Walter Blith (*The English Improver*, 1649), who enforced his arguments by references to the Scripture, and between 1630 and 1649 a large area of the fens was reclaimed. Drilling of grain, instead of broadcast sowing, was advocated by Plat and Gabriel Plattes, "the Corn-Setter," and both Maxey (1601) and Worlidge (1669) invented machines for the process. Live-stock was neglected. Thus Worlidge, whose *Systema agriculturae* (1669) was popular, devoted three pages out of 217 to "beasts." In every other direction useful suggestions for agricultural improvement were made. Despising book farmers and distrusting promises, successive generations of agriculturists waited for ocular demonstration.

By 1700 turnips were cultivated in Norfolk and Essex, and Andrew Yarranton (*Improvement by Clover*, 1663) induced Worcestershire to use clover on "ryelands" exhausted by long tillage. But their cultivation was local. Even the genius of Jethro Tull failed to convert Oxfordshire and Berkshire to turnips, clover or sainfoin. French vine culture taught him to sow crops in rows and to keep his land clean and stirred. He perfected a drill, drilled corn and turnips, kept hoes going and grew heavier crops more cheaply than his neighbors. His *Horse-hoeing Husbandry* (1731), to which Queen Caroline subscribed, embodies his researches into plant life and the essential principles of scientific agriculture. Farming on his system became a fashionable pursuit among great landlords like Charles, Viscount Townshend, who retired from public life in 1730 and set himself to improve his Norfolk estates, revived the obsolete practise of marling, introduced turnips and clover into field cultivation, initiated the four-course rotation of cereals, roots and artificial grasses, drilled wheat and turnips, kept more stock and verified the maxim that "a full bullock yard and a full fold make a full granary." His zeal for roots gained him the

name of "Turnip Townshend," although outside Norfolk turnips were still classed with rats as Hanoverian importations. To make the movement general some stronger impulse was needed than example. It came from the growth of population.

With the reign of George III began the industrial revolution which transformed the distribution of population and wealth, as well as the face and life of the country. In 1760 agriculturists numbered two thirds of the total population, and their income exceeded half the national revenue. In 1828 landowners, tenants and laborers had dwindled to a tenth of the population and their income to a tiny fraction of the whole. Population shifted from the south to the northern coal and iron fields. While implements of production remained simple, agriculturist and manufacturer shared many businesses; machinery applied to production sharply differentiated them and made them mutually dependent. Large factories absorbed domestic industries and small manufacturing centers concentrated their workers in towns and created huge markets for food. Meanwhile the standard of living rose. In 1760 the mass of the people consumed rye or oats and rarely tasted fresh meat; the new population demanded white wheat bread and fresh beef or mutton.

Roots and artificial grasses increased the yield of grain crops; they also supplied the winter keep which facilitated improvements in livestock. Hitherto cattle were valued for milk or draft and sheep for wool; neither was studied as meat producers. Robert Bakewell, of Dishley, Leicestershire, revolutionized the science and art of stock breeding. He succeeded best with New Leicestershire sheep. But according to his principles and methods other breeds of sheep and cattle were rapidly improved for specialized purposes. In average weight beef cattle rose from 370 pounds in 1710 to 800 pounds in 1795, and sheep from 28 pounds to 80 pounds.

Large scale production cheapened manufactured produce. Arthur Young applied the principle to agriculture. He contended that factories for food needed capitalist landowners and large farmers on long leases. Young's doctrine met with instant success. Landowners like "Coke of Norfolk" spent millions on equipping farms with houses, buildings, roads and fences. Their estates proved their best investment. Tenants, possessed of capital, adopted recent improvements, carried more stock, employed

more manure, grew heavier crops and with rising prices profited by long leases. Davy's lectures embodied in his *Elements of Agricultural Chemistry* (1813) marked the union of "Practice with Science." But population pressed hard on production. Under corn laws which encouraged exports or prohibited imports when prices were above or below fixed levels, exports of home grown grain (1697-1801) exceeded imports by 11,000,000 quarters. After 1792 England ceased to export grain. Throughout the French wars (1793-1815) the corn laws were continuously suspended and foreign imports encouraged. But the quantities obtainable were infinitesimal. Stimulated by famine prices, every available acre was cultivated for bread, and the system of landlord, tenant and worker was almost universally established. Accordingly, in 1841, 16,500,000 people were fed from home grown food and England set Europe an example in farming.

In this industrial transformation village farms perished. When the Tudor revolution exhausted itself, enclosures proceeded slowly until under George III they again advanced with revolutionary rapidity. Behind both movements the driving force was industrial progress. Tudor governments opposed enclosures for wool because they threatened depopulation and bread scarcity. Hanoverian legislators encouraged enclosures for grain growing and stock feeding because they increased employment and averted famine. Demands for food necessitated maximum productivity. But village farmers could not introduce roots and grasses on open fields which after harvest were grazed in common, rest their exhausted arable, vary its cropping or grow fodder for their half starved stock whose scanty manure was wastefully distributed. The mediaeval system hindered food production. From the north, west, southwest and southeast it had almost disappeared. But it still predominated in Yorkshire and the midland, eastern and southern counties. Between 1760 and 1820 at least 4,000,000 acres of common meadow, arable and pasture were enclosed by acts of Parliament and redistributed as farms in individual occupation, owners being awarded compact freehold blocks equivalent in value to their scattered strips and common rights. Leaseholders for life, copyholders by inheritance, squatters with twenty years' occupation, were treated as owners. Rent paying occupiers and settlers near common pastures or wastes received nothing for the loss of cow

keeps, poultry runs or firing. When factories absorbed domestic industries, thousands thus became exclusively dependent on agricultural wages. The same loss of supplementary earnings forced small holders to sell their awarded freeholds and share their fate. Landless laborers, pauperized by high prices, low wages, ill judged poor laws and the financial collapse which followed the peace of 1815 sank during 1815-36 into a dependence from which allotments, cottage gardens, small holdings, the franchise, free education, old age pensions, health insurance and wage boards are slowly raising them.

IV. AGRICULTURE ON THE CONTINENT IN MODERN TIMES. The opening of the modern era about the turn of the fifteenth century, with its inauguration of thoroughgoing changes in many spheres of economic activity, influenced agriculture in a relatively slight degree. To be sure, signs were not lacking that agriculture was seeking new paths, but they were confined to areas distinguished by special fertility and located in the neighborhood of flourishing cities. Districts thus favored existed in northern Italy, in the Rhine country, in Flanders and Brabant and adjoining northeastern France; in other words, wherever the presence of economic and natural prerequisites made agriculture indistinguishable from horticulture. As early as the sixteenth and seventeenth centuries these districts seem to have practised some form of crop rotation, meadow cultivation, proper fertilization and working of the ground. Apparently the country households of a city aristocracy were active there in promoting progressive agriculture. We know, for example, that the first great lowland dikes of the sixteenth and seventeenth centuries were traceable to city initiative. The agricultural writers of the time—Joh. Baptista Porta, Agostino Gallo, Tatti, Tanara, Tarello, Bussato in Italy, Olivier Serres in France, Fitzherbert in England, Joh. Colerus in Germany—addressed themselves especially to this circle of agronomic amateurs. In Germany works of these early writers are known as the *Hausväter-Literatur*, in England as “books of husbandry,” a title by which they are pertinently characterized. They are encyclopaedias of

household management, practical handbooks for the master or the mistress of an aristocratic household. Domestic accomplishments such as cooking, baking and preserving are treated with the same thoroughness as agriculture proper, horticulture or the care of animals. Recipes and household remedies against disease are recommended. Considerable space is given to moral and religious observations.

But the large mass of the rural population was untouched by this growing body of knowledge. Most farms were still in the traditional two-field, three-field and field grass stages. Cultivation was extensive, and although the soil was fertilized the supply of animals was as a rule inadequate both in quantity and in quality. The lack of a ready market for agricultural products checked for a time all further development. The masses of the people still lived in the country and produced on a small scale what was necessary for their sustenance. The few cities then existing were small, and their inhabitants likewise produced most of their food in their own households; the type of townsman of that day, even in the larger towns, was the agricultural townsman, *der Ackerbürger*. To be sure, weekly markets were held in the towns, to which the country people of the neighborhood sent their goods; and, following the cumulative development of international trade, a constant stream of easily transportable agricultural produce, such as wheat, wool, cheese and dyestuffs, passed through the seaports. However, only relatively small quantities found an outlet in this way; the possibilities of sale offered no stimulus toward making the industries capable of increased marketable yield through improved agricultural technique. When in the Rhine country, in northern Italy, in France and other regions of early commercial development the old manorial organization had become obsolete, its dissolution took place gradually, not as a result of the substitution of capitalistic agricultural enterprises for the servile peasant family farm, but because money payments supplanted payments in kind. It has been repeatedly stated that the noble and other manorial estates in the Slavic colonial regions, opened up by Germany (east Germany, the Baltic Provinces, Poland, etc.), early exhibited capitalistic enterprise on a large scale. The statement is based on the fact that, in view of the standards of the times, there was a not inconsiderable wheat export from that region and the inference is sound to the extent that these eastern estates

did indeed represent the germ of a later development into large scale economic enterprises. But originally and for several centuries they too were a part of the system of small scale economy for supplying immediate needs. The fact that because outlets were lacking in these thinly populated districts a certain residue was made available for export, did little to change the situation. Even when an outside wheat trade was organized, production itself with its small scale technique was hardly affected by it. Operations on a large scale in early times are found only in itinerant sheep raising, which was developed in Spain (Mesta, *q.v.*), in Italy and in Greece (Mandra, Dogana, Transhumanz). But this is not to be regarded as an evidence of agricultural progress. On the contrary, it represented a backward step to a capitalistically disguised nomad economy, which hampered more than it furthered the agricultural development of the countries concerned.

The transition in agriculture from the production for immediate needs to production for sale was accomplished with lasting effect only in the second half of the eighteenth century. The strongest impulse in this direction obviously came from an expansion of the market for agricultural products. Mercantilism (*q.v.*) brought with it the development of industry and growth of cities, which led in their turn to an increase in population. The demand for, and the price of, agricultural products rose. Traditional agriculture was not equal to the claims made upon it. The system, employed for a thousand years, was felt to be obsolete, and it was widely believed that agriculture had reached its lowest ebb. This view was valid in so far as the increased demand for agricultural products had led to robbing and exploitation of the soil.

With intense unparalleled energy all the world, led by its rulers, became absorbed in agrarian questions. A wealth of literature was produced, different from the old husbandry books and specifically agricultural and economic in character. Learned societies were formed in the universities with a view to promoting agrarian progress. The problem to be solved presented itself then in the following terms: How could agriculture be freed from traditional and outworn methods of grain growing (based on the primitive field system) and be made more profitable by improvements in stock farming and by the introduction of new plants for cultivation? The start had to be made by increasing and improving the cattle,

for this would supply the chief instruments of production for the new agriculture. The countless difficulties which any such reform would encounter at this stage of agricultural organization are clear. For the most part the fields lay indiscriminately scattered over the village common without being individually accessible. An essential part of this system was the *Flurzwang*, which compelled all cultivators to sow and reap simultaneously, on the day and week decided upon by the community. To cultivate new plants, with varying periods for sowing and reaping, was as impossible for the individual peasant as to cultivate fallow land. But in order to increase the working capacity of cattle and their manure production it was absolutely indispensable to cultivate new fodder plants for the better nourishment of the animals. For in regions other than those naturally provided with grass their nutrition was in a wretched state. Any planned fodder management was still lacking. For nourishment the cattle were in the main restricted to pasturage on the far side of arable land. This pasturage, being communal property, was in the worst conceivable condition.

Hence all progress depended upon success in freeing agriculture from the fetters of collectivism. Only if the farmer became free to make his own decisions was a rational high yield economy feasible. This was the objective held in view. Soon it appeared that the nearer the farm approached the optimum size dictated by economic considerations, the more feasible was progress on the technical side.

England at this time enjoyed certain advantages, as compared with the continent. In connection with the enclosures there had developed a system of large scale leaseholding based on tenant entrepreneurs and divorced from any mixture of patriarchal elements. By the eighteenth century agricultural technique here had developed to such a degree that it was regarded as a shining example by continental contemporaries who sought to emulate it. In France they were filled with enthusiasm for replacing the manorial, small tenant economy by large leaseholds according to the English pattern. In this way, on the basis of *grande culture*, they hoped to win a place in the sun of rising capitalism for the landed aristocracy, which had become entirely estranged from any agricultural activity of its own as a result of substitution of payments in money for feudal dues. This agrarian program found its economic philosophy in the physio-

cratic doctrine which sees the source of all wealth in the *produit net* of agriculturally exploited territory and hence looks upon large holdings, administered by wealthy entrepreneurs, as the desirable unit of cultivation. Development in this direction, however, was almost completely blocked by the radical way in which the revolution disposed of feudalism. That France remains a country of preponderantly small peasant holdings is due to the revolution itself and to the Code Napoléon, which provided for the distribution of the commons and permitted the division of real property.

When in eastern Europe feudalism disappeared in the early and middle years of the nineteenth century, the economic foundations of agriculture were at first left undisturbed. But afterwards, as before, the small peasant holdings were worked almost exclusively to meet individual needs and to support the landed aristocracy which, generally speaking, was itself not agriculturally active. No attempt was made either to abolish collective controls or to interfere with the age old, minute division of land to which the Slavic peasants were accustomed. Even when in the seventies Russia and Rumania developed into grain exporting countries there was little change in that respect. The agrarian reform had left the peasant's acute craving for land unsatisfied. To still that hunger he was compelled to resort to additional leasing and was ready to raise export grain for the large landowner under the form of share tenancy; either he gave up half his harvest as compensation for the leasehold or he worked an area equal to his own for the landowner during the whole agricultural year. In this situation no compelling incentive was offered to improve and intensify production. Notwithstanding a constantly increasing grain export quota before the war, east European agriculture remained extensive in character. In Russia the retention of the common village field contributed likewise toward checking agricultural development—the *obshchina* was a truly communal institution with periodically recurring distribution of arable land. Stolypin's agrarian reform of 1906, which sought to effect a change in this, could not be completely worked out before the World War.

Germany had a different development. Here, as in neighboring Denmark, the dissolution of the manorial system was planned in advance and effected with a view to uncovering new opportunities for agricultural development.

The landed proprietors had begun as early as the eighteenth century to dispense with certain restrictions on agriculture. But full opportunity for development was given only at the beginning of the nineteenth century by the so-called emancipation of the peasants, which abolished the various forms of dependence on an overlord, along with the remnants of the former collectivism. Of course there was little change in the situation then existing in localities like the Rhine country, where already in the Middle Ages manorial rights had been commuted into a conglomerate of rent charges, and where consequently there had developed an economically independent, small peasant agriculture which resembled the regime in neighboring France. The similarity was further strengthened by the fact that the region retained the French inheritance law introduced during the short lived Napoleonic regime. Yet the disadvantageous consequences which may otherwise occur in small scale agriculture were absent here as well as in the adjacent countries, Belgium and the Netherlands. Small scale agriculture is not in every instance obsolete. It is adequate to certain claims made upon it—as, for example, in the valleys of the Rhine and its tributaries, where the trade situation is favorable and where specialized intensive cultivation of wine, flowers and vegetables, as well as intensive stock farming, can be carried on.

Thanks to the way in which the dissolution of the manorial system was connected with the consolidation of intermixed strips into compact plots and with the distribution of communal property, the rest of Germany and Denmark succeeded in establishing peasant holdings and independent farms that were efficient even as to size and shape. The existence of such farms led to the appearance of efficient agriculturists, genuine entrepreneurs capable of organizing mass production in agriculture. For Thaer, whose name is indissolubly associated with the history of German agriculture in the first half of the nineteenth century, agriculture was an art of obtaining the highest possible net yield by procedures based on calculation and observation. He founded the first higher agricultural school in Germany and, stimulated by study of English agriculture, succeeded in introducing annual rotation of straw and leaf crops. Apart from the favorable consequences for plant growth this rotation led to an increasing emancipation of agriculture from the one sided predominance of grain cultivation. The earlier

agriculturist, bound hand and foot by tradition and communal regulations, might farm well or ill according to his ability or industry, but the measure of his own initiative was narrowly limited. On the other hand the landlord of Thaer's assumptions was expected to farm "right" or, in modern idiom, "rationally." The progress that started with Thaer was furthered by Liebig. His teaching disposed of all the mistaken ideas on plant nutrition which survived down to his time. Liebig proved that certain mineral substances were indispensable for plant nutrition, and that if the soil was not to become gradually exhausted it had to be replenished by the direct introduction of the withdrawn mineral substances. The absolute quantity of raw materials was not of importance; what mattered was the presence of *all* the raw materials necessary for the plants. While the introduction of crop rotation and of field cultivation of fodder plants by Thaer gave the agriculturist greater freedom with respect to stock farming, Liebig's mineral theory made him more independent in the production and use of fertilizer. For even though animal fertilizer did not prove to be superfluous to the extent that Liebig had believed, still the farmer was no longer restricted to the fertilizer produced on his own farm. Farms heavily stocked with cattle and with a large fodder output were no more practical than lightly stocked farms, which might through purchases in the market make themselves independent of their own fertilizer production. The farmer was now able to specialize in those branches of agriculture to which his farm was peculiarly adapted by natural and economic conditions. He was also in a position to manipulate his productive activities in such a way as to take advantage of important market fluctuations. This affected most favorably the productive efficiency of the individual farms and of agriculture as a whole.

The history of Germany and of the territories bordering it on the north and west indicates the main line of progress followed by continental agriculture during the nineteenth century. Here lie the regions of most intensive exploitation with the highest expenditure of capital and labor per unit of area. The indices of a high degree of intensive cultivation are especially clear in this region: high consumption of artificial fertilizer and (in connection with it) a high average of gross output; intensive cultivation of hoe crops; and a reduction of sheep in favor of cattle and pig raising.

After the beginning of the nineteenth century continental agriculture was considerably stimulated by the increase in demand for its products due to the growing industrialization of the various countries and concentration of population in the cities. These favorable marketing conditions seemed to be seriously endangered, however, when in the late seventies the development and cheapening of transportation made it possible to bring to the markets of the old civilizations the transportable agricultural mass products—grain and fodder above all—of the countries with the most favorable conditions of production. To shut the door against all foreign imports was impossible, since it would have involved such a serious rise in the agricultural price level that industrial development would then have suffered. Internal production might be subsidized by protective tariffs, but this could not completely eliminate the danger. The farmer of industrial Europe responded to the change in the situation by a decisive reorientation of production in the direction of increased output of animal products. Competition with the products of foreign tillage might be hopeless but need not be so in the case of animal products, which are more difficult to transport. This shift in agricultural production was further stimulated by an increase in demand for animal products, since with growing urbanization meat has come to occupy a larger place in the diet of the mass of the people and meat consumption has grown in greater proportion than bread consumption.

The production of grain, therefore, was completely displaced from its leading position and intensive grazing succeeded it wherever the quality of the soil permitted. But even where mixed agriculture was retained the production of livestock was increased; this was facilitated by foreign importation of certain varieties of fodder. In the last years before the war the value of German animal products was almost twice as high as that of vegetable products. The small countries bordering on the industrial center of Europe—Denmark, Holland, Switzerland—were most strongly influenced by this development. They used their favorable proximity to this center to develop an agricultural export economy with high priced products, mostly animal, for the provisioning of neighboring industrial territories, especially of England. The German farmer also profited, except for a few years of excessively low prices. If we can speak of an agricultural depression, it affected

primarily the east German grain and potato growers. Even they, however, could remain above water because of protective duties on grain and the possibility of using part of their potatoes for the production of alcohol. To be sure, their condition remained unfavorable as compared with that of the farmers of western and central Germany. For the latter not only enjoyed better marketing opportunity—they also had in sugar beet culture a branch of production that fitted precisely into the new economic situation. With the help of migratory labor from eastern Europe these favored farmers produced the raw material for an export industry and utilized the waste products as fodder in animal husbandry.

In summing up, we may repeat that the development of agriculture on the continent shows striking contrasts as regards both periods and regions. The reasons for these must be sought in the general economic development of individual districts and in the manner in which the transition from feudal and collective controls to a free agriculture was effected. The strongest motive force in agricultural progress has always been improved market conditions. This generalization is amply supported by our examination of the early periods in regions of active business and commercial life and is suggested still more forcibly by the nineteenth century developments in central Europe. Although the agricultural production of the industrialized continent was insufficient to meet its own needs in food and fodder, still it succeeded in fitting itself into the international pattern of the agricultural market in a way that furthered its own agricultural development.

V. AGRICULTURE IN THE UNITED STATES.

The history of American agriculture from the beginning of the first permanent settlements to the present time has been to a large degree the history of the colonization of a great imperial domain of virgin land and the transformation of farming from a simple, practically self-sufficient, pioneer occupation into a modern business organized on a scientific, capitalistic and commercial basis. As a constituent part of American history closely interwoven with other phases of

the life of the American people, it may be conveniently divided into three periods: first, colonial foundations (1607–1776); second, frontier and plantation (1776–1860); and third, the agrarian revolution and the settlement of the Far West (1860–1930).

The need for land was the impetus for the early colonial foundations; it was “. . . the master passion which brought the men of the seventeenth and eighteenth centuries across the sea and lured them on to the frontier. Where hundreds fought for freedom of worship and release from political oppression, thousands saw in the great unoccupied lands of the New World a chance to make a living and to escape from their landlords at home.” Thus the acquisition of a freehold was the ruling purpose in the settlement of America. Agriculture became the predominant interest of the colonial period. Even those who by occupation were fur traders, fishermen, sailors or merchants generally devoted part of their time to farming.

Land in England during the seventeenth century was held under a modified feudal tenure. Attempts were made in the proprietary grants to transplant some of these survivals to America. The quit rent system met with opposition and resulted in failure. The first settlements were made on the communal basis; but this plan was soon abandoned and individual holdings in fee simple were adopted as the only feasible method of attracting immigrants to the land. Practically every one could acquire land. In New England each settler was granted a certain number of acres as his share in the colony. In Virginia there were three methods of acquiring land: bills of adventure, head right and meritorious service. Land was easy to get and whatever the method of acquisition the grants in all instances amounted substantially to a free gift. In New England the small farm was the rule. The same may be said of the middle colonies, except in the case of the large manorial grants in the Hudson River valley which, however, remained uncultivated until they were broken up into small holdings. In the South large plantations were the rule, the average size of the Virginia estate being about 5000 acres.

The colonial period was necessarily a time of experimentation and adaptation. European plants and animals were acclimatized; and European systems of land tenure and methods of cultivation were adjusted to the conditions of a frontier environment. This was a period of marked improvements in English agriculture.

Turnips, root crops, clovers and cultivated grasses were being introduced. Scientific crop rotation was superseding the wasteful two-field and three-field systems of farming in Europe. The colonists brought with them a knowledge of this experience.

In addition they took their first lessons in American farming from the Indians, from whom they learned the best methods of raising the indigenous crops as well as the most economical method of clearing and preparing the land for cultivation. The colonists were therefore the beneficiaries of a knowledge of plants and animals and of the methods of agriculture acquired by centuries of costly experience both in the Old World and in the New.

Notwithstanding this rich inheritance of agricultural knowledge and practises it was geography after all that constituted the determining factor in shaping the economic development of the colonies, with the result that distinct types of agriculture based on environmental rather than human differences developed. Topography, resources and climate explain the courses of development in New England, the middle colonies and the South. New England was broken by small mountain chains and the arable portions of land were small. This region was adapted to a diversified rather than a specialized system of farming, supplemented by the fur trade, lumbering, ship building and the fisheries. The broad Atlantic coastal plains in the South, on the other hand, with their bays and navigable rivers serving as highways of commerce into the interior and with the illimitable supply of arable land stretching from river to river, and the genial climate, encouraged the dispersion of population and the development of an agricultural civilization based on a high degree of specialization in the production of a few great commercial staples.

Agriculture throughout the colonial period was in a primitive and backward condition. It was fettered by tradition and superstition. Little attention was given to the rotation of crops and to the preservation of soil fertility by fertilization. Since land was plentiful and labor scarce, the colonists economized labor rather than land. Their work was to take possession of the virgin land, to prepare it for cultivation and to select the plants and animals best adapted to the new environment.

The westward movement of pioneer and planter into the Mississippi valley is the dom-

inant fact in the history of American agriculture from the revolution to the Civil War. The occupation of the old Southwest before the revolution and the conquest of the old Northwest by the southern backwoodsmen during the continuance of the struggle marked the beginning of this advance. The Louisiana purchase and the acquisition of Florida followed, thus giving the United States an agricultural empire of vast proportions with a magnificent system of waterways which furnished outlets to the sea. Land hunger attracted the settlers to Texas and "manifest destiny" lured them on into New Mexico, California and Oregon, which were formally annexed to the national domain by the middle of the nineteenth century, while the rapid advance of settlers into this great imperial domain was made possible by the federal policy of land disposal.

The settlement of the Mississippi valley, already begun before the revolution, received a great impetus after the establishment of independence and, although retarded somewhat during the Napoleonic wars, was greatly accelerated after the War of 1812 when westward migration from the older sections of the country and from Europe began to take place on the most unprecedented scale in modern history. By 1860 the eastern half of the Mississippi valley had been added to the settled area, and the frontier had been pushed westward across the Mississippi River to the great plains.

American agriculture during the early part of the national period was a continuation of the types of farming practised in the colonial period. Colonial plants and animals and methods of agriculture were adapted to the new areas reached in the course of westward migration. Grain raising, stock raising and plantation agriculture became the established systems of farming, supplemented by truck gardening and fruit growing. Several types of farming may be distinguished: the frontier industrial unit, the farm and the plantation. The frontier industrial unit consisted of a small allotment of land. This was occupied in many cases by only a single person or a family whose attention to farming was limited to supplying the necessities of life which supplemented the proceeds of hunting and trading, the primary concern of the individual or group being the protection of life rather than the accumulation of property. The farm consisted of a larger unit of land which required the attention of the farmer and his family. The routine was more regular.

Commodities were produced not only for family use but also for the market. Additional help might be required; but such assistance was only intermittent. There was no sharp distinction between the farm owner and his workmen. In the South the farmer might have recourse to hired labor or he might buy a few slaves. The plantation was a comparatively large unit of land the management of which was entrusted by the owner to overseers who directed a labor force of considerable size. There was a high degree of specialization, attention being given largely to the production of one or two staples for the market. Slave labor was the rule; but free wage earners might be employed. There was a sharp distinction between the owner and his workers. These three types of farming might exist side by side; one type might succeed the other in the same locality; or one type might exist independently of the others.

The United States had by 1830 become differentiated into three great economic sections, each section devoting itself more and more exclusively to the production of those commodities for which it was best adapted by nature. New England was becoming a manufacturing-commercial section. Some abandoned farming altogether and migrated to the rising industrial centers, while others were induced to follow Horace Greeley's injunction to "go west." The remainder stayed on the farms. Western competition compelled the New England farmer to abandon grain farming; and the growth of the home market enabled him to turn, in well defined areas, to specialized commercial agriculture such as beef and wool production, dairying, market gardening, fruit raising and, in the Connecticut valley, tobacco growing. Agricultural societies were formed and improved implements and methods of farming were introduced. Agriculture was being transformed from the self-sufficient to the commercial state.

The Northwest, on the other hand, with its extensive areas of woodland and prairie country entered upon a period of rapid expansion and the production of surplus products for the market. A number of new factors contributed to this development, among which may be mentioned: the policy of the federal government which enabled a settler after 1820 to purchase a farm at \$1.25 an acre; the migration of settlers from the East and the Old South and the rapid growth of European immigration in the forties and fifties; the extension and development of water and rail transportation; the invention

and introduction of improved farm implements and machines which were destined later to revolutionize the methods of farming; the growth of markets in the East and South, and also in England following the repeal of the corn laws in 1846; the improved methods of communication, such as weekly and daily newspapers and the telegraph; the rapid growth of the merchant marine; and, finally, the establishment of agricultural societies. The Northwest was becoming the surplus grain and livestock section of the country.

Although the South presented a variety of agricultural types and conditions, the plantation system clearly predominated there. Cotton superseded tobacco as the leading commercial staple. By 1830 cotton had become "king"; no nation has ever possessed such a great monopoly of an essential raw material of industry as the South now came to possess in the case of this staple. Cotton and slavery became the basis of the rural economy of the South. There were variations of course within the plantation system, dependent upon the character of the soil and the labor requirements in the several areas. There were plantations devoted to the raising of cotton, tobacco, sugar cane, rice and indigo. Negro slave labor was well adapted to the production of these staples. There were also many small farms in the several plantation districts of the South; but they were located in the regions of inferior lands which were not so well suited to the plantation system.

There were thus created and established two rival systems of agriculture, the origins of which date back to the beginning of the colonial period: the one democratic with small holdings, diversified farming and free labor; the other aristocratic with large plantations, specialized farming and slave labor. These two systems, based on physiographic and racial differences, though mutually complementary, became engaged in a long sectional contest for the control of the West and for supremacy in the national government.

The Civil War marks the beginning of an economic revolution in the United States which is characterized by two related lines of development, industrial and agricultural. The industrial revolution was the change from hand labor in the home to machine production in the factory; while the revolution in agriculture was the transformation of farming from a type of pioneer self-sufficiency into the scientific capitalistic commercial type.

The factors contributing to the agricultural

revolution were the existence of a vast empire of virgin land and the liberal policy of the federal government beginning with the enactment of the Homestead Law of 1862 in transferring this great heritage from public to private ownership; the rapid increase of population and immigration which supplied the labor force for nearly four and a half million farms carved out of the public domain during this period; the invention and popularization of labor saving implements and machinery and the consequent transformation in the methods of farming; the extension and development of transportation and communication which connected the local markets with the world market; the expansion of home and foreign markets which absorbed the rapidly growing surplus products of the farm; and the establishment and development of various agencies for the promotion of scientific knowledge relating to agriculture, among which may be mentioned the federal and state departments of agriculture, agricultural colleges and experiment stations, farmers' organizations with their economic, political, social and educational functions, and the farm press. By 1914 the transition of farming from the pioneer into the commercial stage was completed. Agriculture became interwoven with the fabric of national economy, giving rise to complex problems of production, distribution and exchange, which were demanding solution as the nation entered upon a period of reorganization and readjustment.

The population of the United States continued throughout this period to be predominantly rural. The census of 1920, however, showed the majority of the American people living in towns and cities, only 48.6 percent of the population being classified as rural. In 1920 the number of persons over ten years of age employed in farming declined to 26.3 percent; while the number engaged in manufacturing and mechanical industries was increased to 30.8 percent. This is a fact of considerable importance in marking the emergence of the United States into an agrarian-industrial state. The number of farms was increased from over two millions in 1860 to over four and a half millions in 1890 and to about six and a half millions in 1920. The average number of acres in farms and the average number of acres of improved land in farms remained fairly constant throughout the period. Meanwhile increased land values were reflected in the growth of tenancy. The number of farms operated by tenants in-

creased from 25.6 percent of the total number of farms in 1880 to 35.3 percent in 1900 and to 38.1 percent in 1920. These figures tend to show that the proportion of farms operated by tenants had become somewhat stabilized during the first two decades of the twentieth century.

The areas described by the familiar terms "corn belt," "wheat belt," "dairy belt" and "cotton belt" became practically determined during this period. In an area lying northeast of a line drawn approximately from the mouth of Chesapeake Bay to the northwest corner of Iowa, the agricultural population had rather definitely devoted its energies to the production of dairy products, truck, potatoes and fruit on the basis of domestic market demands. To the southwest of this line the area including most of the states of Ohio, Indiana, Illinois, Iowa, Missouri and portions of a number of bordering states was devoted to the raising of corn and the production of meat animals, depending for the most part on a domestic market but disposing of some 15 percent of its pork products on the foreign market. To the west and north of the corn belt was the wheat belt, one fifth of whose product was dependent upon a foreign market, while the remaining four fifths were used to supply domestic demands. In the South, where cotton farming had occupied an important position for a long time, about one half of the production was shipped abroad to the industrial centers of Europe, while the other half was consumed in domestic markets.

The passing of the public lands was accompanied by significant changes, which characterize American agriculture in the twentieth century. Among these changes may be mentioned: the rapid rise in land values and the consequent transition from extensive to intensive farming; the decline of agricultural exports due to the tariff policies of European countries, the development of other sources of supply and the growth of the home market; the utilization of inferior lands by irrigation and drainage; and the reorganization of rural life which broadened the farmer's outlook, brought him into contact with the business world and awakened in him a realization of his educational needs and opportunities.

These changes are all of a permanent nature. The principal agricultural problem of the present is therefore one which calls for a fundamental and thoroughgoing readjustment of the farmer to his changed economic environment. It appears that the foreign demand can no longer

be relied upon to absorb the exportable surplus at prices generally remunerative to the farmer; and that consequently the prosperity of the farmer depends very largely upon the growth of the domestic non-agricultural population for the creation of a market which will absorb at profitable prices practically the entire domestic supply of agricultural products. This means that the farmer must henceforth plan his agricultural production to meet cash home market demands. The time has come, in short, when less dependence is to be placed on the great world staples such as wheat, cotton and pork, upon which the major agricultural activities of the United States have hitherto been based, and more attention must be given to the production of perishable and semi-perishable commodities such as dairy products, vegetables and fruits.

VI. AGRICULTURE IN THE ORIENT. *China.* In China perhaps more than in any other country of the Far East the dominant factor in the agricultural situation, as in every other, is the extraordinarily dense population. On the other hand the population is itself affected by the unusually intensive agriculture. For in this country cultivation of the soil has probably reached its absolute maximum of intensiveness. The extent to which intensive cultivation has been carried can best be judged by a comparison of the number of settlers per square mile of cultivated land in China and in the United States.

According to the best authorities a square mile of cultivated land in Chihli has from 550 to 2000 settlers, while in Shantung the number is about 4200 and in the rice lands of Chekiang may run from 2270 to 6860. Other estimates indicate an average for all China of 1783 people per square mile, most of whom live on agriculture alone, with no subsidiary industry of importance. This is indeed a striking contrast to conditions in the United States, where in the year 1900 there were 61 persons per square mile of arable land.

In China as in Japan rice is the chief product of cultivation, especially south of the Yangtse valleys, where wet rice cultivation is the rule. The other important products of southern

China are sugar cane, cotton, tea, bamboo and the mulberry tree for breeding silkworms. The distinctive features of the agriculture of northern China are the loess soil and the adequate and timely annual rainfall, which not only makes artificial irrigation unnecessary but results in the production of a remarkably large crop. The north cultivates primarily wheat, barley, millet, buckwheat, maize and extremely large quantities of dry land rice, cultivated without inundation of the fields. Latterly the soy bean has become very important as an article of export even to Europe, and in the provinces of Shensi and Shantung the cultivation of cotton is considerable.

While China thus cultivates a large variety of products, rice nevertheless remains the most important both as the national food and as the basis for the largest financial enterprise. It is in its cultivation that Chinese skill in producing the largest returns per unit of soil has been most evident. The soil is most intensively cultivated on the very smallest farms, for in wet rice cultivation the young plants attain their first growth in a very small area. They are not transplanted for nine or ten weeks, a sufficient time in which to mature another crop, wheat for example, in the rice fields, and thus put the soil to every available use. Nor is anything ever lost to the soil. All natural fertilizers, especially human excrement and the accumulations of the cities, are applied to it. The fertilizer is often mixed with earth before it is used in the fields, and a humus in which young plants quickly take root and develop is thus artificially generated. These methods are all very simple and to the point; they are practised with minutest care, excessive work and the most primitive tools. In many regions even the plow is still made of wood with iron mountings, and other tools are extremely primitive.

The feudal system prevailed in China down to the second century before Christ. It was destroyed in a series of struggles of which the causes remain obscure even today. We are equally at a loss to know the sources of power upon which China's remarkable political system was built. The state in China is particularly important for agriculture, especially in the rice area, because ultimately it is in charge of the water supply. The distribution of water, its conveyance to even the smallest parcels of land, careful consideration of all interests, especially preservation of the cultivation itself, are of the very greatest importance. Successful and con-

tinuous administration is of value not only to the farmer, however, but to the state as well, for its regular tax revenues are dependent on potential agricultural yield, which in turn rests on the water supply. Irrigation thus forms a foundation for the development of an extensive administration, a connection which Max Weber has shown to have existed also in the history of Egypt. With the decay of political power the water supply in China was administered locally but on the whole, it would appear, adequately. Today China's 200,000 miles of canals are the foundation of a major part of her agricultural system.

Throughout the country the agricultural yield does little more than support the farmers themselves, and more than half the crop is probably consumed at home. Many villages are compelled to remain self-sufficient economic units solely because of the difficulties of transportation. Much freight is transported by human beings. On the primitive cart roads only the clumsy, heavy, two-wheeled wagon can be used, and overland export, except by canal or river, is almost impossible. Consequently hundreds of thousands of farms are practically unaffected by national or international division of labor, and returns are very meager. The farmer's income is more than modest even if we express it in terms of the means of subsistence. The poor household never knows a luxury, and existence must be eked out with less nutritive foods, millet especially. Meat is practically unknown except on the greatest holidays, and the poultry raised is quite inadequate. King estimates that nine times as much poultry is raised in the United States as in China, and 180 times as many cattle. Buddhism is partially responsible for this situation, but there is also the necessity of using all that the soil can yield for direct human consumption.

The houses in the villages are constructed miserably, built only of clay, for the most part, and consisting of a single room in which only the raised sleeping place is heated from below. Grass, roots and dry twigs must serve as the scanty fuel, because the forests have been denuded. It is only very recently that systematic forestry has been undertaken in a few places, as for example in the neighborhood of Nanking. The wretched clothing of the people in the villages is frequently made at home or, when possible, acquired second hand. These conditions are aggravated where, as in some parts of southern China, a system of tenancy prevails

and a large part of the crop must be delivered to the landowner. In such regions, therefore, a radical peasant movement is widespread.

In spite of this poverty Chinese agriculture forms the basis for one of the most stable of economic systems. During the recent years of profound national and municipal changes and of extensive industrial developments, it has scarcely altered. For this the primitive condition of the roads is largely responsible. The construction of modern highways or the spread of a network of railways would soon produce a different situation. Even today it is petroleum, as a means of illumination, and tobacco that induce the peasant to sell his products and to strive for increased production. Whether a more inclusive marketing system could appreciably increase Chinese agricultural production is by no means certain. It is questionable whether anything more can possibly be extracted from the soil by new means, for instance artificial fertilizers. However, the unused time of the winter months constitutes a potential source of considerable income for the peasants, particularly for those in the north, and home industry or seasonal work in factories could very greatly increase their productivity.

Yet even if certain possibilities of development are conceded, under present circumstances they would fail to yield a larger income per family. The tendency of the population to increase is still very strong in China, and increased production would assuredly soon result in correspondingly increased population. The Chinese family system which values highly a large number of children, in combination with the Chinese inheritance law which results in division of property among the sons, has led to minute subdivisions of territory. No falling off of this tendency has hitherto been observable, not even, as in Europe, in well-to-do circles. So long as the ideal of birth control fails to make itself felt in a practical way in China, no decided improvement in living conditions is to be expected.

Japan. Technically Japanese agriculture very strongly resembles that of China. Both are conditioned by an extraordinarily dense population and by similar products of cultivation, chiefly rice and silk. Where the average number of people per square mile for the United States

was 61 in 1900, and for China has been estimated at 1783, in Japan the average number is 2350 per square mile. Conditions and methods of production are therefore very similar in the latter two countries. But in its legal system and its position in the state, agriculture in Japan is distinctive.

The feudal system which was in force in Japan from remote antiquity until 1868 was most consistently and successfully developed in the reign of the Tokugawas, from 1600 onward. By that period the whole country was centrally organized and regulated, with the landed nobility, the daimios, subject to the central authority. About the courts of the daimios, who enjoyed different degrees of rank and influence and varying extents of territory, were grouped the samurai, the retainers or knights. The important thing about this warrior class was that it stood outside the cycle of production and depended for support on a rice revenue which was transmitted by the overlord. The position of the daimios is thus in contrast with that of the European nobility who administered their own lands in organic economic connection with peasant farms. In Japan all the ground was worked by the peasants, who had to give to the overlords a very large part of the gross yield, from one third to two thirds, usually about a half. As early as the eighteenth century the European feudal system was an obstacle to intensive development of agricultural resources, not only because it made impossible the support of a dense population but also by reason of the constant political catastrophes which it brought in its wake. The Japanese feudal system, on the other hand, made possible a stable, intensive agricultural system. As early as 1721 the population of the Japanese islands was estimated at twenty-six million, although Hokkaido, the most northerly of the islands, had not been settled at that time. This corresponds roughly to the present density of population in Poland or France. The figure was consistently maintained into the nineteenth century. It could not increase very materially since there was no agricultural margin, but throughout the reign of the Tokugawas it did not decrease. European history offers nothing parallel to this situation.

With the transition to the new empire the revenues derived by the nobility from the peasants disappeared. They had indeed previously suffered numerous contractions, as the overlords had sought to broaden the founda-

tions of their own existence at the expense of their retainers, the samurai. But the collapse of the feudal system did not produce an unburdened, economically independent peasantry, for more or less extensive estates took the place of political overlordship. Today such large estates comprise approximately half the rice fields, which are administered under a system of tenancy.

Japanese economic life rests on a very narrow agricultural foundation, as only between sixteen and twenty percent of the total land can be used for agricultural purposes. Altogether there are thirteen million acres under cultivation, and actual cultivation is very intensive. On an average one family lives on a *le* (two and one half acres); and since the agricultural population constitutes half the total, two families have to extract their means of subsistence from this area. This is possible only by reason of a high yield per unit of area and very meager nutrition. The rapidly increasing agricultural population has no agricultural outlet. Korea, with the same area as Japan, has sixteen million inhabitants, but the Korean climate does not appeal to the Japanese peasant. Neither does the climate of Manchuria or of Hokkaido. Consequently the agricultural population grows more and more dense or overflows into the cities.

Japanese agriculture is not, as such, comparable to Chinese. The differences consist primarily in a much more modern exploitation of the soil, in the use of better tools and in more intensive intercourse with the city. The Japanese village is not a self-sufficient unit; the rural like the municipal population can read and write, its needs are supplied largely by modern industry. Consequently the peasant is a dynamic element in Japanese economics, he zealously strives to increase his income, he is exposed to all the temptations of his age. From time immemorial the Japanese has had many more wants than the Chinese peasant; he also participates in the finer enjoyments of Japanese culture and consequently finds the narrow limits of possible production doubly oppressive. The attempts to increase production are therefore quite as intensive as the political endeavors which aim to increase the peasant's income by lowering his rent. Indeed the agricultural situation in terms of the development from tenancy to independent ownership is today one of the most difficult social problems that Japan has to solve. Moreover, here as in China the inherently strong tendency of the family to increase pre-

sents one of the greatest obstacles to the adjustment of consumption to possible production.

India. Agriculture remains, as it always has been, the chief support of the Indian people. Nine tenths of the population live under distinctly rural conditions, a proportion which, in spite of industrial development, has remained practically unchanged. Three fourths of the people are actually dependent upon agriculture, forestry and stock raising for their livelihood. This proportion rose from two thirds twenty years before the last census (1921). Moreover the business and professional classes often own rural land, and most of the new industrial laborers retain a home connection in the village.

India is a sub-continent and possesses a great variety of climates and soils, yet there are striking similarities as to the appearance of the villages, the farm tools and methods used, the crops produced and the standards of living. The most divergent types of cultivation are in Bengal and Burmah, where there is a heavier and more reliable rainfall than in other parts of the country. At the opposite extreme are semi-desert regions like Sind. But most nearly characteristic of India are the dry areas, sometimes upland, sometimes alluvial, of the Punjab, the United Provinces, the Central Provinces, Hyderabad, Mysore and the Madras and Bombay presidencies. It is the agriculture of these regions which either prevails in, or furnishes the main features of, nearly all Indian rural economy.

India as a whole supports 177 persons per square mile, but in Bengal this figure rises to 578, in the United Provinces to 414, and in some almost purely agricultural districts there and in Bengal to as high as 700. Only about 40 percent of the total area is under cultivation, and about 25 percent is classed as "culturable waste," most of which is not economically cultivable. A considerable part of the land under cultivation is very poor. Part of it lies fallow, often for years at a time; usually something like one third of the total area is actually sown. Since 15 percent of the cultivated area produces two crops, there is about one crop-acre per person dependent on agriculture per year.

The land in India is subject to a great variety of rights. A large estate (*zemindari*) may belong to a single landlord (*zemindar*) or to a village community jointly. Such estates were settled by the East India Company on tax collectors and

others who had claim to them at the end of the eighteenth century, the government of the company at the same time renouncing the right ever to increase the tax assessments. Eighteen percent of the land is under this "permanent settlement," 30 percent is in large estates "temporarily settled" and 52 percent is held by peasant proprietors of various grades. Some of these hold with special rights, while still others hold with special limitations. Likewise there is a variety of types of tenancy. There are tenancy for life and tenancy from year to year. Some tenancies are permanent with fixed payments; some are transferable, some heritable. Beneath the tenants are the village menials and field laborers, who belong to low caste or non-caste groups. Some of these are *de facto* serfs. But the proportion of hired laborers is small; in many sections there is only one hired laborer to four and one half independent cultivators, and in places like eastern Bengal this figure sinks to one hired laborer to eight independent cultivators.

Ownership is widely but unevenly distributed. In the Punjab, which ranks second in amount of land per cultivator, over 43 percent of the owners' holdings are less than three acres in extent. In irrigated areas the holdings are still smaller, one third of the owners often having less than one acre. Most holdings lie scattered in several fragments over the village. A large proportion of the land is tenanted, but generally the tenant has a high degree of security. Rentals are usually paid in cash. The two (united) provinces of Agra and Oudh had in 1924 and 1925, respectively, 76 and 81 percent of their total cultivated areas tenanted; yet only 20 and 15 percent, respectively, were annual tenancies from year to year.

Village houses in India are usually small, built of mud or thatch with almost no furniture to beautify or make them comfortable. However, caste rules require them to be kept clean according to old standards, and they are suited to the hot climate. Food is mainly the coarser grains and vegetables, milk, oil and chillies. A very large minority of the people are always underfed. Clothing is simple and for the great majority inadequate. Often the same untailored cotton cloth is clothing by day and covering by night.

Typical Indian agriculture is a kind of "dry-farming," since, although some areas have abundant moisture, most regions depend upon a monsoon which is seldom too heavy and often too light. In the poorer areas cultivation is decidedly extensive but in well watered regions

of rich soil it is exceedingly intensive. One fifth of the area sown is irrigated. Half of the water used comes from canals, mostly government owned, one fourth from wells and one eighth from "tanks" or ponds. In order to retain moisture there is little deep plowing but considerable working and smoothing of the surface mulch. Methods and tools are old fashioned but not so ineffective as they at first appear to an occidental. They are suited to a hot, dry climate and are fairly adapted to the whole situation. Bullocks furnish the necessary power, while the light, cheap implements which are used are made to go over the ground several times. The most striking deficiencies in this agriculture are the starving of cattle and of soil. Many non-milking cows are kept because they are marks of wealth and of piety. In dry seasons these animals devour every blade of grass and shrubbery so that in many places only thorn bushes survive. The soil receives almost no humus, and with the lack of wood and coal the cow dung is taken for fuel. Artificial fertilizers have been neglected and night soil wasted. More fertilizers and more intensive working in rows and hills are needed. The government has spent much on agricultural schools, experiment stations, demonstrations, etc., but it has had marked success mainly in the selection and production of better varieties of cattle.

Facilities for marketing and finance are little developed and unfavorable to the farmer. They are furnished mainly by local men who belong to merchandising and money lending castes. The small, ignorant cultivator in a land of uncertain crops is often forced to borrow, and he usually borrows or buys on credit from the person to whom he must later sell his produce. His only security is his crop and his land. At best he disposes of his crop under a handicap and at worst he loses his land. Terms of lending and purchasing are commonly secret; the farmer is a bad risk, and with his ignorance and timidity is always at a disadvantage. Rates of interest range from 10 to 75 percent per annum. Repudiation is often the only possible settlement.

Eighty-five percent of the cultivated area of India is used to produce food crops, and seven eighths of these are consumed in the country, the larger part in the villages where produced. Rice ranks first, occupying over one third of the total area sown. Then come wheat, *jowar*, *bajra* and other crops suited to a dry climate. Pulses provide protein for a vegetarian diet. India is

the second producer of both cotton and tobacco and has a monopoly of jute. Yields are generally light, cotton, for instance, averaging under half the amount per acre which is produced even in the United States. Modern transportation and communication have induced a tendency toward growing money crops, but since there are only 2.2 miles of railway per 100 square miles, as compared to 8.42 miles per 100 square miles in the United States (which has only one eighth the average population density), this applies only to a small proportion of the country. With increasing industrialization tendencies to change will undoubtedly be strengthened, but at present throughout the greater part of India it is the centuries old systems and methods of agriculture which prevail.

See: LAND TENURE; VILLAGE COMMUNITY; IRRIGATION; FOOD GRAINS; FAMINE; DRY FARMING.

VII. GENERAL PROBLEMS. *Agricultural Resources.* The agriculture of the tilled field does not and cannot occupy so large a proportion of the earth's surface as may be supposed. Much land is too dry for the cultivated crop, some of it is too wet and some is too steep or stony. Much land is too cold and some is too hot and unhealthy. As a result of these handicaps less than five millions of the fifty millions of square miles of land upon the earth are cultivated fields. The application of present knowledge can scarcely double the area even after generations of peaceful labor.

New discoveries in the science of the soil tend to diminish rather than to increase our estimate of soil resources. After a long period of floundering with unclassified soil facts it has recently been discovered by Russian students that the development of earth or rock material into soil goes through a cycle—young, mature, old. The startling thing is that climate dominates the character of the *mature* soil almost without regard to its geologic origin. For example, the mature soils of the rainy tropics are of very low fertility because the elements of fertility, usually present in mature soil, have been leached out by rain. Java, which might seem to afford contradictory evidence, is probably populous because its volcanic soil was recently blown out from the interior of the earth and therefore is new or young soil. The Central American banana plantations are on the recent outwash of alluvial fans at the foot of the mountains and are therefore also on young soils. As a result of too

much leaching, rainy western Europe has mature soils of low fertility that have been worked into suitable conditions for good agriculture by great labor and can be maintained only by great care. The early abandonment of newly cleared land in the western part of the state of Washington in the United States, where the climate is almost identical with that of England and western France, also dovetails with the newly discovered theory of climatic causation of soils. Good agricultural lands in that type of climate are made and maintained only by hard work and intelligence.

The black prairie soils of the middle western regions of the United States furnish an illustration of the theory of climatic causation of soils. Between the wet forest of eastern Texas and the subhumid and treeless northwestern Texas, and also between the humid forests of Indiana and the semi-arid sagebrush lands of western Nebraska, there is a transition in rainfall and in natural vegetation. Between each of these two regions of rainfall contrasts and their resulting vegetative contrasts is a wide belt of grassland. Grassland makes black soil—"black-waxy," as it is called in Texas. Of similar origin are the black wheat lands of central Kansas, eastern Nebraska, eastern Dakota, Manitoba, Saskatchewan and Alberta. These black soils are a transition belt between the eastern and northern forest (humid) and the sagebrush plains (dry). Similar zones of transition in rainfall, in vegetation and in soil are found in the black land grain fields of other continents. The limited black land area in Argentina has made that country a grain exporter. In Eurasia the Black Belt sweeps from the Black Sea through Russia and far into Siberia. Australia has a little strip, as has the Sudan.

This black soil is the prime grain land of the world. Trains and reapers reached it in the last third of the nineteenth century. The resulting deluge of cheap grain demoralized the agriculture of eastern North America in the last quarter of the last century and caused western Europe to shift from grain farming to livestock and dairy farming. Produce derived from these black soil belts is one of the principal factors in the recent growth of cities. The human race is now in the golden age of urban food supply, because we are skimming the cream from this rich accumulation of past ages by the soil robbing process (agricultural mining) that everywhere has characterized frontier agriculture. Of course science and commerce may en-

able us to maintain this advantage in part by substituting soil conservation (a process involving a greater investment of labor) for mining. Unfortunately this problem is scarcely realized as yet in the United States, although substantial areas are already ruined in most of the states.

Types of Agriculture. The variety of soils, of climates and of cultivations has given us many types of agriculture, most of which are still in existence in some form. The patch agriculture of the tropic forest without draft animals which provides the sustenance of millions in Africa, in the East Indies, in the Philippines and in tropical America can be seen in typical form in the Congo forest. Here at the beginning of the dry season the villager cuts the undergrowth in order to make a small clearing in the forest. He then kills the larger trees by burning or girdling them. Near the end of the dry season he burns the trash and with the aid of sharp stick or hoe plants shoots of cassava, banana and plantain, the seeds of sorghum, corn (secured from white men), rice, beans, peanuts, pumpkins and other vegetables. These the women cultivate by hand and hoe. In two or three harvests the fertility of the leached tropical soil is exhausted. The African gardeners must abandon the garden and make another. When they have tilled all the good garden spots near the village, they move the village. Thus migratory or patch agriculture is explained. This type of agriculture is followed promptly by the returning jungle.

In the West Indies, immediately beside the small, self-sufficient little farms (*conucos*) are the wide expanses of the silver-green fields of the great commercial sugar cane plantations. These must be large in order to support the great mill necessary for the extraction of the sugar. Here also are the banana plantations, which must be large in order to supply bananas enough to furnish cargo for the steamships. In similar tropic expanses the modified jungle becomes a plantation of cacao trees or rubber trees. On the higher tropic lands both east and west other large areas are covered with tea and coffee trees. The workers all get wages and buy supplies at the store as does the farm laborer of Denmark or Illinois.

Plantations are an old institution on the West Indian Islands but are just starting in Africa with the slightly modified forest of oil palms and the new cacao plantations. These plantations rarely have any system of soil preservation or

crop rotation. They have escaped impoverishment by moving as the patch agriculture moves. Cuba, the greatest sugar grower, has the blessing of a wide, nearly level limestone plain, therefore an area of rich land; and Java, the next largest sugar grower, has its volcanic soils. So has Hawaii.

The resemblance of the cotton plantation system of southern United States of America to the roving patch agriculture of the tropics is striking. It has a rainy climate, leached soil, the forest and the Negro. In slave days the cotton plantation migrated to a fresh clearing in the forests, thus abandoning the old fields. Its chief difference is the greater destruction of soil in America through erosion caused by plowing. In recent decades this destruction has been increased by the introduction of chemical fertilizers which have impoverished soils to produce more cotton when they would otherwise have been abandoned to the healing mercies of the briar patch.

Irrigation agriculture is probably second or possibly first in the order of origins. It now supports approximately a third of the human race. Its great early developments were in Egypt, Babylonia, the Indus valley and China. Babylonia and India depend upon large canals. Therefore they require a stable society which means strong government. Hence agriculture here tends to fall with empire. Egypt is more fortunate. Her irrigation depends upon an orderly overflow of the river. Therefore she has had a persistent minimum of agriculture and a continuous occupation by millions of people. Just now with a strong government engaged in water storage enterprises Egyptian agriculture is extending its area through canal building.

Irrigation agriculture has several elements of permanence. The more important are the natural fertility of the unleached, arid land, the irrigation water which nearly always carries fertilizing elements, and the flatness of the land which prevents soil erosion. Its defects are the tendency to seepage, involving great drainage costs, and to the collecting of alkali, which makes desert spots that can only be cleared up by costly arrangements for drainage and washing.

The permanent aspect of irrigation agriculture is particularly evident in the oriental paddy field so extensively developed in China, Japan, India, Ceylon and Java. It has even been developed to an astonishing perfection of

technique on mountain slopes by the Igarots of the hill country of Luzon. Their terraces laboriously constructed for conducting water have made upon mountain slopes one of the world's most spectacular and permanent forms of agriculture. The successful rice field may be called a permanent agriculture because it does not wash away, and the fertilization with human excreta has caused it to endure for millennia. It is interesting to observe the capture of most of its essential elements (except the preservation of fertility) by the machine agriculture of America in the rice plantations of Louisiana, Texas, Arkansas and California. The irrigated agriculture of the United States has, however, added no other new features of importance, representing a transfer both of crops and of technique from the Mediterranean area.

The Mediterranean countries having an open winter with some rain, and a dry summer, have two kinds of agriculture: the irrigated orchard and garden spots, mostly small peasant holdings; and the upland in wheat or barley, sometimes alternating with legumes (pottage). By this process of growing grain by the use of the plow, the uplands of Greece, Italy, Syria and other Mediterranean countries have been in large measure destroyed despite the saving of small scattered areas by terracing. The Old World non-irrigated terrace is spectacular but surprisingly small in area, and it saves only a small percentage of the hill lands. An exception to this record of soil destruction in Mediterranean lands is to be noted in the few plains not irrigable but flat enough to allow plow agriculture for long periods. California is like the Mediterranean countries in almost all respects save the absence of any large upland area suitable for grain, and the great development of the fruit industry resulting from the vast American market and the large export trade that has followed standardized output.

The agriculture of northwestern Europe is on a much more permanent basis than that of southern Europe or eastern United States because of the small proportion of hill land, the gentle rainfall and the summer rain which makes turf and permanent covering. The fallow field system followed by crop rotation, including legumes, has produced the great agriculture that has been perfected there in the last half century with the aid of commercial fertilization and the partial application of science to agriculture. Carefully worked out crop rotations result in grain farms, dairy farms, meat pro-

duced on fattening farms and in shipments of potatoes, beet sugar, fruits and vegetables.

The European type of agriculture has been transferred to eastern Canada (except the Ontario plain), to New England and parts of New York with no change in crop or technique worthy of mention save a lesser intensity and a greater use of pasture. Farther inland and farther south the European crop list was enlarged by corn, tobacco and cotton. These three crops furnish a new element to the European agricultural technique, requiring as they do wide areas of cultivation throughout the growing period of the crop. They all require a climate of summer rain, which happens to fall in torrents that carry away the soil loosened by tillage. This is destroying American soil resources at a rate never before equaled in human history, a rate that makes agriculture impossible for millennia over wide areas.

Pasturage, the lowest form of land utilization, is a kind of residuary legatee inheriting those large areas of land that will grow a little grass or edible browse but not a plowed crop. The nomads following their flocks in Mongolia, central Asia, Arabia and the Sudan have developed well adjusted cultures. Similar grasslands in Australia, South Africa, Argentina, Brazil and western North America have been taken by the commercial cowboy and sheep herder. In a few decades they have greatly reduced the productivity of these pastures in nearly all these regions by excess grazing and the introduction of weeds.

Commercial Agriculture, its Tendencies and Problems. The industrial revolution with its machines in the factory, its railroads and steamships, and lastly its machines on the farms, has given us the modern phenomena of cities and commercial agriculture. In 1800 a good locality for agriculture and manufacturing in the home and village was one that produced grain, fruit, wood and grass for milk, meat and wool. A dependable climate was needed to maintain this completeness of local self-sufficiency without serious crop failure. By 1900 manufacturing had been removed to the cities, and a good location for agriculture was one that produced a few crops, or possibly only one if in quantity sufficient to enable the family to sell the surplus and buy needed articles. It takes more stuff to sell and buy than it does to make and use. Therefore the little factory farms of the era of Julius Caesar and John Adams, by which Latium and New England thrived, could not

meet the needs of 1900 and had been abandoned by the thousands in the course of the three preceding decades. By the year 1930 the necessity of still larger sales has become keenly manifest. In addition to his 1900 needs the farmer must now pay for automobiles, gasoline, radios, phonographs, daily papers and many other new things—perhaps even cosmetics. Therefore he needs to produce a much greater quantity of produce to sell than he did in 1900. Many farms which sufficed in 1900 have failed and have been abandoned in widely scattered regions in the decade 1920-30.

Commercial agriculture is depressed. One cause of this depression is that production has increased faster than consumption, and, as the farmer is nearly always without any bargaining power save supply and demand, farm produce has a lower relative price than it had before the World War. The German and English farmers are in a position strangely like that of their American colleagues. We now see that when applied to farm produce one of the staunch theories of the economists is found to be inoperative. For a century we have been told that machine production, which increased the output, would make more wealth for everyone. The farmer has not found this to be the case in recent years. There is a fundamental difference in this respect between food and other classes of goods. Wealth enables a man to buy almost indefinite quantities of factory goods, but wealth does not increase man's appetite for food. Yet more, this, the richest of all generations, eats less than any other. We ride in the automobile, push buttons, pull levers, save energy, and therefore need less food. To make matters worse for the farmer, the American diet appears to be shifting rapidly from a meat basis to one of cereal, fruit and leaf greens, all of which require in their production much less land than meat requires. The use of gasoline for motors has released millions of acres of land that were once required to produce oats and hay for the horse. The chief thing government has done is to stimulate production and produce a glut. The county demonstration agent has helped to break the market by finally teaching the farmer how to increase production. O. E. Baker (U. S. Department of Agriculture) has shown that since 1920 we have decreased the number of cows, and increased the amount of milk; decreased our cattle and increased our beef; decreased our sheep and increased our mutton. The increased efficiencies of agricultural production by way of new and

improved machines, animal breeding and plant breeding are appalling in the number of readjustments that they are forcing upon us. Apparently the process has but begun. Doubtless we can increase agricultural production in the next two decades even more strikingly than we have done in the last two. Knowledge is advancing; machinery is still being improved and its scope widened, as by refrigeration and power on the farm. Business organization in both production and distribution of farm produce will also make great contributions to available supply.

The following are some of the more conspicuous agricultural changes which may be said to be impending because they have already begun in a small way:

(1) *The Large Corporate Farm.* Montana furnishes us suggestive examples of this kind of development. In 1917 that state had about 35,000 farms where wheat was grown. Eleven years later there were but 14,000 farms, but they were growing more wheat. This resulted from the introduction of the tractor which enabled two, three or even four plows to be used at a time. To harvest the enlarged acreage the combined harvester and thresher came into use. Experiments are now being tried whereby a dozen or even two dozen plows are used as a single unit. This may make the farm of twenty to fifty thousand acres as much the unit in its field as the cotton mill with its long rows of spindles is the normal successor of great-grandmother's spinning wheel.

The hay drier is a subject of experiment in several countries. This machine promises to the farmer a considerable degree of emancipation from the vagaries of the weather in humid lands. The successful experiments with a hay drier operating on minimum units of 640 acres almost rival the Montana wheat experience in indicating the economy of large productive units. This change to large scale production may come very soon. It may even be that the one-family farm is doomed to disappear as the effective unit on the world's level agricultural lands.

(2) *Corporate Chain Farms.* The business complexities of the farm unit with its problems of nutrition of animals, nutrition of plants, soil management, maintenance of machinery, maintenance of plant purchases, sales, accounting and labor management show how ready is the farm for the application of those principles of division of function that have made the chain stores and the chain factories so effective economically and so appalling socially. This

process is under way in the Middle West. It began by bankers striving to save themselves from loss. It is impossible to predict how far this form of production management may go. Like cooperation in marketing and purchase it relieves the farmer of tasks which by their inherent difficulty are almost impossible for him to do well along with his other labors. Like the large scale farm, this too promises an increase of production per man.

(3) *Tree Crops.* A large fraction of the world's good agricultural climate and fair agricultural soil is on space taken by hilly land. Therefore it is either unused for agricultural purposes or more commonly it is being ruined by the plow. A whole new series of tree crops might be developed for hilly land—crops that can produce without destroying the land on which they stand. They also have great possibilities for semi-arid lands. Tree crops offer a means of nearly doubling the world's supply of food and of some raw materials during the ensuing century if creative imagination can be applied to the problem.

Millions will probably continue to starve in China, but it is also perhaps true that one of the greatest economic problems of the western world of mechanized industry in the next decades will be the widespread glut both of factory goods and farm products. This is not a problem to be solved in the field, at the work bench or in the laboratory but in the realm of social arrangements.

Economic and Social Position of Agriculture. A big crop meant prosperity in the domestic era in America in 1800 as it does in China today. A big crop in the age of commercial agriculture is often a calamity to him who grows it. In 1926 two or three million bales of cotton went unpicked in the United States, and the rest sold at the price of picking. In the same season some twenty or thirty million bushels of apples went unpicked and the other one hundred and twenty million bushels sold at picking price or less. There is a glut of truck crops in the American city markets almost every month in the year.

Apparently the prices in gluttable markets can only be kept at a profitable point by the aid of legislation or some similar form of group action. The farmer, especially in America, has shown himself peculiarly weak at group action. Hence he is becoming the prey of the groups that are more effectively organized. The manufacturer gets tariffs. The public utilities are guaran-

teed dividends, and many of them are still in a position to water the stock and thus increase the prices that farmers and others must pay. The railroads are guaranteed good wages for their workers and are almost guaranteed dividends. The banks have a secured position favored by law, and many of them regularly make the borrower pay more than the legal rate of interest.

The causes of this helplessness are easy to see. The farmers are divided into regional groups and into crop groups. The social aspect of their business is too complex for most of them to understand. They are scattered over a vast area. Compare them with manufacturers: the manufacturer can reward those who make his legislation, the farmer cannot; the manufacturer knows what he wants in legislation, the American farmer does not. He displays an unbelievable lack of understanding. Thus, for example, there is in Iowa no large city element in the population of the state. The state has a uniformity of soil and climate and surface not equaled in any other of our forty-eight states. The state has uniformity of interests in the produce of corn, oats, hay, wheat and meat. These crops have been sold, since the days of first settlement, in export markets at a free trade price. For sixty years the people of that state have voted for the protective tariff, which increased the price of almost everything they bought and gave them no aid in selling. They did this apparently in the belief that they were promoting their own self-interest. At the same time they sought protective duties on their own products, the effects of which were bound to be illusory, since these were products of which the nation had a surplus for export. It appears obvious that any program for placing agricultural prices on a parity with industrial must rest upon some form of control of price or of production.

Even in the United States there are a few examples of agricultural price control. Cranberry growers living in restricted areas seem to have an effective price control. Milk producers for certain limited markets have achieved the same result and show a moderate prosperity in the midst of an American farm situation characterized in general by long working hours, very low actual wages and usually no dividends on the investment. Many observers can see in this situation definite evidence of a trend toward serfdom.

Yet there is Denmark, an agriculturally organized nation. In the United States the farmer is

the legislative prey of other classes. In Denmark he controls legislation. The American farmer is a producer for the middleman. The Danish farmer is his own middleman. Indeed Denmark is a most interesting study for the student of social affairs. How is it that they can so far eclipse the Americans? Russia too offers a field for interesting study. There the farmer with his crop and the city man with his fancy stuff are openly struggling to get the better of the trade bargain by means of favorable legislation. China and Japan furnish another very interesting agricultural situation. The industrial revolution which is beginning in the factories probably cannot be extended to agriculture, for in both China and Japan the small farm worked by hand methods and largely by man power is made to produce double crops by processes that machines cannot duplicate. Since commercialization would mean decreased production, the present agricultural system is likely to continue indefinitely. But the condition of the oriental peasant might be considerably improved by the establishment of village industries; and village factories within walking distance of oriental farmers could find millions of workers for a part of the year. A similar labor supply is available in Europe and America. Regional planning is one of the important social reconstructions required by the coming era. Among many other things we may need to restore the conditions of employment that prevailed before the industrial revolution. In those days of household economy the population worked in the fields in summer and at indoor handicrafts in winter. It appears possible that it may now be both economically and socially profitable to let factory machinery stand idle in summer while the farm worker attends to crops; agricultural machinery has long stood idle all winter while its user did little or nothing.

AGRICULTURE, GOVERNMENT SERVICES FOR. As early as 367 B.C. the Roman Republic recognized the importance of agriculture and the rural population by adopting a measure limiting the size of private estates acquired from the public lands. Numerous other laws relating to agriculture followed, practically all of them dealing only with land ownership. European legislation in the Middle Ages and the Renaissance was concerned chiefly with permitting enclosures of common land and with prohibiting increased wages for farm labor.

It was not until the eighteenth century that the agricultural revolution in Flanders, later moving to England, and the notable decline in the population of France, caused serious governmental consideration of effective scientific and economic aid to agriculture. The first steps were informal and tentative, such as the importation of a few pure bred cattle and the extension of some measure of state aid to agricultural societies.

In the following century government services for agriculture developed chiefly along two important lines: first, the formation of organizations for research and education; second, the extension of special credit privileges to farmers, the development of reclamation projects, the protection of agricultural labor, and the development of regulatory activities as to foods, feed stuffs and the like.

Practically all nations of agricultural importance now have government departments of agriculture, primarily for research and the dissemination of its results. Most of these departments were founded in the nineteenth century, either separately or as divisions of other departments. In some countries the experiment stations are under direct control of the Department of Agriculture. In practically all countries, however, most of the stations are governmental institutions, as are the colleges of agriculture and the agricultural secondary schools. Notable experimental work has been done under governmental auspices in Great Britain, Germany, France and, particularly as to soils, in Russia. In practically all European countries excellent college and university courses in agriculture are offered, these institutions being almost invariably state supported. Secondary education in agriculture has been developed

to probably the highest degree in Denmark.

Governmental services to agriculture have been developed most extensively in the United States, except as regards certain advanced forms of social legislation affecting agriculture. In colonial days subsidies and bounties were offered by both the British and colonial governments to stimulate various lines of agricultural production. The raising of silkworms especially intrigued the fancy of the politicians, and financial encouragement was extended to this industry in Virginia, Georgia and South Carolina. Hops, indigo, hemp, lumber, pitch, tar and sheep were also subjects of governmental assistance. The aid extended consisted variously of premiums, land grants, instruction, the repeal of duties, and the payment of bounties on the products when shipped to England.

Subsequently, when the United States attained its independence, its most influential citizens expressed special interest in agriculture. Either they had had personal experience in farming, as had George Washington and Thomas Jefferson, or they recognized its importance in the development of the young nation. Their thinking was influenced by knowledge of what Arthur Young and other proponents of the agricultural revolution had done in England (Young corresponded extensively with Washington), and by the agricultural theories of the French physiocrats, which are plainly evident in Jefferson's eulogies of the farmer. In his last message to Congress in 1796 President Washington advocated government support for agricultural institutions in these words:

"It will not be doubted that, with reference to either individual or national welfare, agriculture is of primary importance. In proportion as nations advance in population and other circumstances of maturity this truth becomes more apparent, and renders the cultivation of soil more and more an object of public patronage. Institutions for promoting it grow up supported by the public purse, and to what object can it be dedicated with greater propriety? Among the means which have been employed to this end, none have been attended with greater success than the establishment of boards composed of proper characters, charged with collecting and diffusing information, and enabled, by premiums and small pecuniary aids, to encourage and assist a spirit of discovery and improvement. This species of establishment contributes doubly to the increase

of improvements by stimulating to enterprise and experiment, and by drawing to a common center the results, everywhere, of individual skill and observation, and spreading them thence over the whole nation. Experience accordingly has shown that they are very cheap instruments of immense national benefits."

The proposal was lost in Congress, however. The early governmental support given to agriculture was not federal, but state. State aid was extended by Massachusetts to the Society for Promoting Agriculture as early as 1792. New Hampshire extended aid to county societies in 1817. Similar aid was extended by various other states. The money received by these societies was employed largely in publishing articles on agriculture, and in giving premiums either for exhibits of crops and livestock or for new discoveries in agricultural practice.

Aid was first extended by the United States government in 1839, when Congress appropriated \$1000 for collection of agricultural statistics for agricultural investigations, and for the procurement of cuttings and seeds for free distribution among the farmers. The work was placed in charge of the Patent Office because Henry L. Ellsworth, then commissioner of patents, had already begun volunteer distribution of seeds and plants from abroad and had shown special interest in governmental aid for agriculture. Appropriations continued to be made to the Patent Office for agricultural purposes for more than twenty years, the high mark being reached in 1855, with \$50,000. In 1862 agriculture was placed in a separate department with a commissioner at its head. In 1889 the commissioner of agriculture became secretary of agriculture with a place in the president's cabinet.

The Department of Agriculture has shown steady development, being now by far the largest organization in the world devoted to agricultural research and the dissemination of agricultural information. The total number of employees is approximately 22,000, and the annual expenditures are more than \$150,000,000, two thirds of which is for road construction, subsidies to states for research and extension work, and conservation purposes.

The other work of the Department of Agriculture includes the following types of activity:

(1) Research, such as experiments in animal and plant breeding, investigations in pure

science underlying agriculture, horticulture, forestry and similar subjects; experiments in methods of controlling animal and plant diseases and pests; in soils; in the economic problems of agriculture, such as farm management, individual and cooperative marketing, and the discovery of new uses for farm products. The actual practices of farmers on farms and in cooperative and other organizations are studied. Extensive statistical data are gathered.

(2) Extension work, the dissemination of facts discovered through research, carried on in the Office of Extension, in the Office of Information and in individual bureaus. Each year the Department distributes approximately 30,000,000 copies of its publications. It presents authentic agricultural information through more than 100 radio stations. It exhibits educational motion pictures before many gatherings of farmers. It supplies agricultural copy to newspapers and agricultural journals. It prepares numerous exhibits for large fairs. Largely in cooperation with the states, it carries on extension work through county agricultural agents, home demonstration agents and boys' and girls' club agents. Demonstration has proved especially effective.

(3) Eradication or control of plant and animal diseases and pests through organized campaigns, independently or in cooperation with state agencies. It is interesting to note that since the passage of the Plant Quarantine Act in 1912 only one major agricultural pest, the pink bollworm, is known to have become established in the United States.

(4) Service work, such as administration of the national forests, the weather service, crop and livestock estimating, the market news service, and inspection service on farm products at shipping points and terminal markets.

(5) Regulatory duties, comprising administration of approximately forty laws, including the Food and Drugs Act, the Meat Inspection Law, Plant and Animal Quarantine Acts, the Migratory Bird Treaty Act, the Cotton Futures and Cotton Standards Acts, the Grain Standards Act, the Warehouse Act and the Packers and Stockyards Act.

The Department of Agriculture is headed by the Secretary of Agriculture and the Assistant Secretary. There are five directors, covering respectively the fields of scientific work, regulatory work, extension, information, and personnel and business administration. Legal matters are handled by a solicitor and his staff. Bureaus and offices, organized on the basis of

subject matter, comprise experiment stations, weather, animal industry, plant industry, forestry, chemistry and soils, entomology, biological survey, public roads, agricultural economics, home economics, plant quarantine and control, and foods, drugs and insecticides. The last two offices are organized for the enforcement of laws, while the others are engaged mainly in research. The library, containing 205,000 volumes, is the largest agricultural library in the world. Its facilities are employed by scientists outside, as well as within, the Department of Agriculture.

In the same year that the Department of Agriculture was established Congress also passed the Land Grant Education Act, which offered public lands to each state for the establishment of colleges of agriculture and mechanical arts. Such colleges now exist in every state in the union, and in Alaska, Hawaii and Porto Rico. In some cases the Land Grant college is a separate institution, while in other instances it is connected with the state university. A number of southern states have separate Land Grant colleges for Negroes. State experiment stations were subsidized by an act of Congress in 1889, and most of the existing state stations owe their founding to this act, although several had been established earlier. Later legislation (1925) has furnished still more extensive federal funds to these stations, giving them special opportunity to develop investigations in agricultural economics and in home economics. The federal government itself maintains stations in Alaska, Guam, Hawaii, Porto Rico and the Virgin Islands. Extension activities, aside from the publishing of agricultural information, began with lectures before farmers, which gradually developed into farmers' institutes. The institutes began in the sixties and reached their maximum influence between 1900 and 1915. In 1914, 8861 institutes were held, with an aggregate attendance of 3,050,150. Most of the institutes lasted one or two days, a few extending over three or more days. From 1916 on, the institutes declined. Their place has been taken largely by the system of county agricultural agents and county home demonstration agents, involving actual demonstrations under local farm and home conditions. During the same period boys' and girls' clubs have developed extensively, their members undertaking practical farm and home projects and also endeavoring to interest their communities in higher standards of agriculture and rural life.

All of the modern extension activities are increasing group thought and action as a habit in country neighborhood life, and are stimulating individual ambitions for more satisfying homes and communities. The federal government gives aid to high schools offering instruction in agriculture and home economics.

Large sums are expended by the states for agricultural education, research and extension. Certain of the federal appropriations are conditional upon equal expenditures by the states. Many states also pay the expenses of boards or departments of agriculture engaged chiefly in gathering and supplying information of use to agriculture, although other government services are also furnished. For example, seeds and plants, either imported or developed in the United States, are at times distributed by the United States Department of Agriculture or by state agricultural colleges to farmers qualified to make use of them in practical field tests. For many years a vast quantity of seeds was distributed by the Department of Agriculture through members of Congress, but this practise came to be recognized as undesirable and was abolished June 30, 1923. Rural free delivery of mail, which has brought the farmer into close touch with the thought of the nation generally, was begun in 1896. It now reaches approximately 24,282,000 people. The good roads movement, on which vast sums have been expended by national and state governments, has also been a potent means of communication for farmers. The weather service was recognized as especially useful to agriculture as early as 1890, when Congress transferred it from the army to the Department of Agriculture. Its forecasts have been of incalculable value to agriculture, especially since they have been disseminated by radio.

Extensive projects have been undertaken for land reclamation. Swamp lands have been reclaimed only under state laws, inasmuch as the federal government by legislation in 1849, 1850 and 1860 granted all the federal swamp lands to the states in which they were situated. Practically all of the drainage enterprises under state laws consist of corporate districts or county drains, the cost in both cases being met by assessment against the land benefited. Projects for reclamation of dry land by irrigation have been undertaken under both state and federal auspices. State aid has generally been undertaken in much the same way as in the case of swamp lands—through irrigation district

laws, making the lands liable for the cost of their own reclamation. The first state or territorial law for irrigation was passed by Utah in 1865. In 1894 Congress passed the Carey Act providing for patenting large areas of desert lands to several states on condition that the land be reclaimed by irrigation and sold to actual settlers. Eight years later the federal government actually entered into reclamation projects. The work has been administered by the Department of the Interior. Early projects proved largely disappointing because of failure to consider the actual needs of settlers aside from the provision of sufficient water. Beginning in 1923 more adequate methods have been undertaken with the purpose of determining, before construction is authorized, the feasibility of a project and its dependability for actual settlement of farm homes. While in some cases reclamation projects have proved successful, in others they have resulted in dissatisfaction to the settlers and in losses to the federal government. In view of the overproduction of various cash crops in the United States in recent years, there is a strong feeling against the reclamation of further land for the present.

Closely related to land reclamation is the California land settlement plan, the only example of its kind in the United States. Under this plan the state buys land, provides irrigation and drainage works so far as necessary, subdivides the land into farms, farm laborers' allotments and town lots, and sells the land on easy payments to actual settlers. Two colonies have been established under the law, but the time since their establishment has been too short to predict the extent of their ultimate success. Similar projects have been proposed for adoption by the federal government.

All these government projects possess the advantage of being backed by the public treasury and consequently of being able to carry settlers through periods of depression such as are almost universally characteristic of agriculture, and for the elimination of which no government has yet found adequate means. They possess such disadvantages as may be associated with contemporary political control.

Cooperative marketing, doubtless the most important project on the business side of agriculture in this century, has received both federal and state aid. This has consisted in the furnishing of information and in the passage of legislation enabling these organizations to

function effectively. Delaware is the only state having no law governing cooperative associations. The Capper-Volstead Act, passed by Congress in 1922, places upon the secretary of agriculture responsibility, upon the one hand, for protecting the public against unwarranted use of power by cooperatives and, on the other hand, for protecting the associations from unwarranted prosecution. The federal government has also established a division of cooperative marketing in the Department of Agriculture for the purpose not only of studying effective practices in cooperation but also of supplying useful information as to market conditions to the cooperative organizations. Until very recently the United States, in contrast to some European countries, has not extended financial aid to cooperatives. However, through the Federal Farm Board established by the Agricultural Marketing Act of 1929, the federal government intends to encourage the organization of cooperatives and to aid in financing their operations in the hope of promoting orderly marketing of agricultural products.

Considerable service has been rendered to farmers by means of extension of credit. The Federal Reserve Act of 1913 permits five-year loans on land to farmers to the extent of 25 percent of the capital and surplus of the bank. This is only an incidental feature of the law, however. Much more extensive facilities are offered by the Federal Farm Loan Act passed in 1916, following a study of European practices. The establishment of the Federal Reserve System added a certain flexibility in the handling of short term agricultural paper. The Agricultural Credits Act of 1923 set up federal intermediate credit banks which may loan directly to cooperative associations, may rediscount for other banks, and in turn may rediscount with the Federal Reserve Banks. It also set up agricultural credit corporations to deal in agricultural, including livestock, paper.

Long term credit to farmers is also provided by a number of states. Minnesota, Oregon, North Dakota and South Dakota have special systems for the purpose of supplying farm credit. The most elaborate system is provided by the Bank of North Dakota. Arizona, Colorado, Idaho, Maine, Montana, North Dakota, Oklahoma, Oregon, Utah and Wyoming offer a small amount of rural credit through the administration of the school land or other public land funds. Some states also have legislation providing for credit unions or cooperative credit associations.

Various special services to farmers have been offered by certain states. North Dakota, through the efforts of the Nonpartisan League, offers the most conspicuous example. In 1919 the state established, in addition to the Bank of North Dakota, a mill and terminal elevator, a home building association, and hail, fire and tornado insurance. The home building association proved unsuccessful and disbanded. The other agencies still exist; after weathering the agricultural depression, they have achieved a fair measure of success, in spite of the prevalence of opposition to the Nonpartisan League. Several other states maintain insurance departments which carry certain risks, most important of which, from the specific standpoint of the farmer, is hail insurance. For the most part, however, hail insurance, like fire insurance, is in the hands of joint-stock or mutual companies.

On the whole, government assistance to agriculture in the United States has been limited to the provision of information and advice. This is manifestly due to the high degree of individualism among American farmers, which in turn is attributable, in considerable measure, to the great territorial area, and the fact that farmers, for the most part, live on their separated farms and not in villages, as in certain European countries.

In many other countries conditions are quite different. For example, in Austria, between 1890 and 1900 cooperative organizations were provided with an elaborate system of subsidies for the export of agricultural products, the employment of specialists, the construction of necessary buildings, and the purchase of machinery. In time, however, this aroused a certain opposition, and some cooperatives were formed with the policy of accepting no government aid. In Belgium, the *comices agricoles*, the technical agricultural societies, are semi-official. In a number of countries agricultural insurance receives special state support. France subsidizes cooperative livestock and some other forms of insurance. The province of Alberta in Canada operates hail insurance on the basis of a tax. Special credit facilities are offered to farmers, especially through cooperative associations, by practically all European countries, while agricultural credit is also available in countries in South and Central America, Africa, Asia and Australasia.

Agricultural labor is protected in many countries. For example, Ecuador, Esthonia and

Spain regulate the hours of labor directly, while in Austria, Czechoslovakia, England, Germany and Poland the hours of labor are fixed by agreement or regulation legally enforceable. In the United States, in which the number of farm laborers is only about half the number of farms, regulation of hours of agricultural labor has always been successfully opposed by owning and tenant farmers.

There are state employment services in many countries. In the United States, however, the service provides largely seasonal labor. Italy is the only country which has compulsory unemployment insurance for agricultural workers. In Denmark and in the Netherlands there is voluntary unemployment insurance under state supervision.

Special aid to agriculture has been given by various governments through land settlement plans. The Australian system is of special significance in that it provides for either individual or colony form of settlement, for the grouping of lands to provide town sites, farm laborers' allotments and regular farm areas, for the organized construction of agricultural improvements, for the selection of settlers on the basis of their fitness, for long-term credit, for the prevention of speculation so far as possible, for the establishment of demonstration farms for advice and instruction, and for cooperative community organization. Denmark supplies state funds to rural and urban laborers of small means for the purchase of small holdings, the purpose being to support the small holdings system, which has been successful in that country for more than a century. Finland has a state land settlement fund for loans to communal societies for settlement on the land. These societies in turn supply credit to the various land settlement undertakings. There is also a state land fund for cooperative societies to supply floating capital to small landowners. In England the colony form of settlement has been put into effect under the Board of Agriculture and Fisheries, the state guaranteeing against financial loss. Each colony is managed by a director, the settler being employed at the current rate of wages, but receiving also a share of the profit from the farming operations. In New Zealand loans have been made by the state to settlers on land since 1894. In Italy the state gives aid to the purchase of land by cooperative societies for agricultural purposes. Various dues and taxes are remitted, and credit up to 80 percent of the value of the land is extended.

Practically all civilized countries have adopted systems for the diffusion of agricultural information. For a long time the colleges and universities were the only source of instruction, and they reached only persons of exceptional ability, training or opportunities. Chiefly since 1900 the movement to reach working farmers and their families with practical information has gained impetus in practically all countries, while greater and greater emphasis has been laid on the study of agriculture in the rural schools and, in some agricultural countries and regions, in city schools also.

The kind of service given to farmers in this field differs in various countries. For example, the several states of Australia maintain more than fifty experimental farms, in addition to approximately twenty times this number of experimental plots on private farms. Thus the double purpose of experimentation and demonstration is served. In addition each state lays great emphasis on personal visits by the experts of its department of agriculture to individual farms. Lectures and demonstrations are given under the auspices of the agricultural bureaus, which are local organizations of farmers for the promotion of agriculture. The Dominion of Canada maintains some twenty-five experimental farms and stations, in addition to demonstration farms and plots operated by the provincial departments of agriculture. It has also a system of agricultural representatives comparable to county agricultural agents in the United States, but responsible wholly to the respective provincial governments. The Farm Women's Institute, which has spread throughout the world since 1899, is a Canadian contribution, as are also rural school fairs. In Chile every elementary school maintains a class in agriculture and a field for agricultural experiment. The teachers are trained by annual courses offered by professors in the Higher Institute of Agriculture. The government gives special short courses in the various branches of agriculture, and also sends special demonstration trains throughout the country to promote better methods of cultivation. Denmark has made one of its chief contributions to agricultural services for farmers in an indirect way through the establishment of the people's high schools. It is due not only to the instruction but also to the spirit developed in these institutions that agricultural cooperation has proved so successful in that country. Denmark also has an elaborate system of lectures by experts paid

wholly or in part by the government for the assistance of practical farmers. There are special schools for small allotment holders, as well as other agricultural institutions. Agricultural education in Denmark dates from 1845. In France each department has a director of agricultural services, assisted by one or more professors of agriculture. Instruction farms, schools of agriculture, schools of home economics and women's institutes are likewise maintained. A system of chambers of agriculture is also provided for by law. In Great Britain research has been carried on very effectively. Most of the counties employ a paid official called an agricultural organizer, who advises farmers and arranges lectures. Belgium employs about thirty agricultural experts, the same number of deputies and a smaller number of horticultural advisers. These men reach the farmers by lecture, demonstration and personal visits. In particular the government requires them to instruct farmers in the advantages of organization. In Germany agricultural experiment and instruction are heavily subsidized by state governments, and much work of high quality has been done. The chambers of agriculture, which are not government bodies, have done much in local agricultural organization and instruction. In Spain there is a law permitting demonstration fields to be maintained cooperatively by villages and district farm schools, the villages furnishing the land, and the schools the technical direction, machines, seed and fertilizer. Comparatively few villages, however, have adopted the plan. The schools are required by law to give short farm courses. Experimental and demonstration work, similar to that maintained in European and American countries, is carried on in China, although on a smaller scale. In Japan there are more than fifty agricultural experiment stations, short courses are offered in both agriculture and home economics, and the lectures are frequently illustrated by lantern slides or motion pictures. Agricultural courses are regularly given in the army to soldiers from rural districts. The government has also distributed large quantities of improved seeds and plants.

The technical agricultural services offered by the government of Soviet Russia are of special interest as representing the point of view of a political system very different from the systems of other nations. The government offers much material assistance to small farmers who will unite into agricultural coop-

eratives, while it prohibits any effort to coerce the peasants into cooperation. The purpose is a great socialized agricultural industry. In addition the government has organized the *Sovkhozy*, or grain producing enterprises. These are large, highly mechanized farms, following largely the practises that are used in modern wheat ranches in the United States. On January 1, 1928, 2,722,000 hectares (approximately 7,100,000 acres) were embraced in the system, each *Sovkhoz* having an average size of 500 hectares. In 1928 the government began a program of more than doubling the extent of the *Sovkhozy*, wherever possible, by adding new farms. By 1933 the government expects to have replaced all primitive Russian plows with modern mold-board plows, of which it is estimated that 7,000,000 will be needed. In the same period it is planned to put 100,000 tractors into the farming industry.

The government has adopted a ten-year colonization plan to settle more than four million people on fertile border lands. Irrigation and other reclamation projects are provided for. Considerable emphasis is laid not only on improving agriculture but on strengthening the border regions economically and politically.

The experimental, educational and extension work in Russia is similar to that in other European countries. In 1927 there were seventy-one agricultural experiment stations and several other laboratories supported by the government.

The International Institute of Agriculture (see AGRICULTURE, INTERNATIONAL INSTITUTE OF), founded in 1908 through the efforts of David Lubin, is the most potent means for international collaboration and cooperation in technical matters connected with agriculture. The League of Nations, through its Economic Consultative Committee, deals with some agricultural problems. Its relation to technical services rendered by governments to agriculture has not as yet, however, become well defined.

AGRICULTURE, INTERNATIONAL INSTITUTE OF. Around 1900 David Lubin, a California merchant, became convinced that agriculture urgently needed an international clearing house for timely information on the extent and condition of crops, and the number and kinds of livestock. He argued that the wise adjustment of agriculture in any country depended upon an accurate knowledge of the industry in other countries. In addition he held that crop areas and conditions were important price making forces which should be a matter of public knowledge. Lubin attempted to interest various governments in the promotion of such an organization. These efforts brought him in touch with the king of Italy, who was impressed with the logic of this enthusiastic American and commended the plan to the favorable consideration of his government. As a result the Italian government sponsored an international diplomatic conference which culminated in the formulation of a treaty signed on June 7, 1905, by the representatives of forty nations. This treaty created the International Institute of Agriculture, with its center of operations in Rome.

The institute is an official organization, supported by governments. Voting powers are regulated in accordance with the financial obligation voluntarily undertaken by each nation. Colonies and dependencies are admitted on the same conditions as are independent nations. The legislative body is the General Assembly, which meets, as a rule, once every two years. Executive responsibility rests

with a permanent committee. Each adhering state has the right to appoint one representative on this committee. The institute has as organs of consultation and collaboration the Agricultural Advisory Committee, the International Scientific Agricultural Council, the International Permanent Commission of Agricultural Associations, the International Commission for Coordination in Agriculture and the International Agricultural Economic Council. The International Scientific Agricultural Council has a membership of more than six hundred experts, representing fifty-three countries and grouped in twenty-three technical commissions which are concerned with special studies and activities.

The institute is empowered by Article 9 of the treaty to deal with the entire range of problems affecting the welfare of agriculture. The one general limitation on its activities is that "all questions relating to the economic interests, the legislation and administration of any particular state must be excluded from the sphere of the Institute." Its most important work is the collecting, compiling and disseminating of agricultural statistical data. It maintains an extensive cable service for keeping in touch with the areas sown, crop conditions and harvest yields of the more important staples. It is at all times cooperating with governments with a view to increasing the accuracy and extending the scope of their agricultural statistics. To this end the institute is attempting to promote a universal agricultural census in 1930.

Such matters as world prices of agricultural produce, agricultural legislation, agricultural cooperation and trade in agricultural produce are being studied by the institute. It hopes to stimulate movements for international plant protection, protection of animals useful to agriculture, standardization of meat inspection, regulation of cheese descriptions, unification of cheese analysis methods, and similar projects. The plans will be worked out at international conferences.

The institute publishes monthly in five languages the *International Review of the Science and Practice of Agriculture* and the *International Review of Agricultural Economics*; it publishes also the *International Year Book of Agricultural Statistics* and the *International Yearbook of Agricultural Legislation*. In addition it issues numerous monographic studies. The number of signatory powers has increased from

forty in 1905 to seventy-four in 1929. The estimated expenditure for 1928 was approximately 5,000,000 lire—\$265,000.

AGUESSEAU, HENRI FRANCOIS D'. See DAGUESSEAU, HENRI FRANCOIS.

AGUSTIN, ANTONIO (1517-86), Spanish juristic philosopher. He was born in Saragossa, studied philosophy and law in the universities of Alcala and Salamanca, and went to Italy in 1535 to study in Bologna and Padua. In Bologna the great Alciati initiated him into the methods of the new jurisprudence. Agustín broke away from scholastic tradition and went directly to the study of the sources. In 1541 he moved to Florence to study the celebrated manuscript of the Pandects; the result of his studies was his first great work, *Emendationum et opinionum libri IV juris civilis* (Basel 1544), a book which aroused the admiration of all scholars. It was followed by a series of studies of constantly increasing importance, one on the *Novels* of Justinian, the manuscripts of which he studied in Venice; another, the splendid work *De propriis nominibus τοῦ πανδεκτοῦ Florentini* (Tarragona 1579) which revealed wide horizons to juristic science. Of the utmost importance in canon law are his corrections to the so-called Gratian Decretal, in his book *De emendatione Gratiani* (Tarragona 1587).

Agustín's theological and juristic learning combined to make him one of the greatest authorities and one of the most frequently consulted at the Council of Trent for the three years during which he was present at its sessions. The papacy entrusted delicate diplomatic missions to him, and in 1574 the king of Spain named him archbishop of Tarragona, where he died in 1586. His labors as a humanist and archaeologist were considerable.

AHRENS, HEINRICH (1808-74), author and teacher in the field of legal philosophy and political science. He was born in Hanover, was a student and later *Privatdocent* in the University of Göttingen, and was professor successively at Brussels, Graz and Leipsic. His departure from Göttingen was made necessary by his part in the revolutionary disturbances of 1831.

Ahrens' chief work was in legal philosophy. His particular contribution in that field was that of elaborating, explaining and popularizing (among savants) the legal doctrine of another German author—the philosopher K. C. F. Krause. According to Krause, law, viewed ideally, is the embodiment of principles that harmonize nature, human reason and God; laws, more concretely, define the modes of progress toward the actualization of that ideal harmony. This "idealistic-organismic" legal philosophy, which Krause set forth in a somewhat mystic spirit and in difficult and technical terminology, Ahrens expressed in fuller, clearer, more realistic form. He is thus known as founder or principal representative of this particular sort of "natural law" legal philosophy. A specific contribution of importance which he made is in his application of that philosophy to the social basis of the state, with detailed discussion of the organic relations between the state and the various smaller corporate associations into which individuals naturally group themselves.

AIDS. The word aid (*aide*, *ayde*) meant originally any aid or subsidy granted to a suzerain at irregular intervals. By custom the lord had the right to call upon his vassals or copy-holders for aids on stated occasions. In general these were the payment of the ransom of the lord when made prisoner of war, and of the expenses incident to the arming of his eldest son when

knighted, the marriage of his eldest daughter and his departure for a crusade. In this original form aids were known throughout feudal Europe, but only in France did they survive feudalism. This article will therefore consider the development of aids in France from the fourteenth century to the revolution.

Toward the end of the thirteenth century, when the great expansion of the royal domain transformed the little Capetian suzerainty into an important state, the resources in men and money that the feudal law granted to the lords, and above them to the king, became quite insufficient. It was therefore necessary for Philip the Fair (1285-1314) and his successors to find new revenues. They tried to force the acceptance of the new and non-feudal principle that to the king belonged the right of taking all the necessary measures, fiscal and military, for the defense of the kingdom. The entire history of the fourteenth century is filled with the struggles which the French kings had to wage in order to levy throughout the kingdom new taxes not allowed by the feudal law. When they obtained these taxes they were usually limited by the condition that these *aides*, taking as they did the most diverse forms (taxes on the sale of merchandise, taxes on salt, taxes on income, hearth-money, etc.), should be collected and expended by the *élus* (deputies of the Estates) and that they be devoted exclusively to the object—generally the upkeep of the army—for which they had been requested from, and approved by, the Estates General.

By a remarkable coincidence even the military defeats of the French monarchy made for progress in this direction. The captivity of John the Good (1350-64) and his ransom, payment of which was a recognized obligation for the entire feudal hierarchy, facilitated the transformation of these occasional *aides* into a permanent tax, and of the *élus* or *surintendants* charged with their administration into royal agents. The skilful policy of Charles V (1364-80) initiated the transformation which, though it was slow and difficult, was completed by the time of Charles VII (1422-61). At the same time that the *taille* was made permanent under this king, the *aides* also became permanent. The ordinance of February, 1436, reestablished them after a long interruption as an indirect tax consisting of a basic rate of 12 deniers to the livre on all sales, plus special taxes on the sale of wines and other drinks. The same ordinance detailed the measures to be taken for

the farming of *aide* taxes—farming which until 1604 was done, not *en bloc*, but separately for each kind of tax and for each province. Thus from that method of collections of *aides* by the *élus* of the Estates, nothing remained but the word *élus*. This continued to be applied, erroneously, to agents who were no longer elective but were appointees of the king and were soon owners of their offices. These *élus* constituted the local fiscal administration in *pays d'élections*, that part of France which had no provincial Estates. Above them were two types of superior officers originally chosen by the Estates General: *généraux sur le fait des finances*, charged with administrative supervision, and *généraux sur le fait de justice*, who as *cours des aides* passed final judgments on all tax litigations.

Henceforth the word *aides*, entirely losing its original general meaning, came to be applied only to taxes on drinks and certain other articles of minor importance. There were considerable local differences in the levying of these *aides*, differences which dated from the very time of their establishment and which were retained to the end of the *ancien régime*. Some provinces and cities had bought themselves free of these taxes, in whole or in part; some assessed the tax at their pleasure; some refused any subsidy even when neighboring provinces granted them; the provinces newly added to the kingdom kept their special regime. Nothing was less uniform than the system of *aides*, and the number of extremely complicated taxes which it included was very large. One of the *aide* taxes was the wholesale (*le gros*), a tax of one twentieth on the sale price, which toward the end of the old regime was collected only on drinks. Another *aide* duty was a tax on the sale price at retail, a rate of one fourth in a few localities and of one eighth in the majority of them. The *aides* included also an unpopular tax which figured prominently in the *cahiers* of 1789, the *trop bu* or *gros manquant*. This was the duty levied on drinks used by the vine cultivators in excess of the quantity fixed for their family consumption, and therefore presumed to have been sold by them without declaration, in evasion of the wholesale tax. It gave rise to house to house searches, against which feeling ran very high when the revolution broke out.

The unpopularity of these *aides* was very great; it is not clear, however, that it was always justified. Ministers who were devoted to the public welfare, such as Colbert, greatly preferred the *aides* to the *taille* and would have

wished to reduce the rate of the direct tax and to raise that of the *aides*. This policy would have been more equitable in a society burdened with special privileges, for although the *aides* themselves admitted of certain very regrettable exemptions, these were far less important than those allowed under the direct tax. The great defect of the *aides* was the confusion to which they gave rise, varying as they did according to locality, and being complicated therefore by a host of vexatious rules. In itself, however, the administration of the *aides* was well conceived; when the law of the 28th of April, 1816, put the tax on drinks in the form that it retained throughout the nineteenth century, it did little more than copy what had been done for the *aides*. For a long time *aides* were included in that group of royal revenues which was farmed out as a unit. In 1780 Necker put them under a separate administration which by 1789 netted the treasury slightly over fifty million livres.

The *cours des aides* were courts of last instance whose jurisdiction extended to the assessment and the levying of only those taxes which were in existence at the time when these courts were established and acquired their power. Consequently they had nothing to do with such imposts as the *capitation*, *dixième* or *vingtième*, which date from the seventeenth or eighteenth century. The word *aides* had thus kept, in this case, the general meaning that everywhere else it had lost. These courts, together with the *parlements* and the *chambres des comptes*, constituted that group of courts of last instance whose officers owned their offices, and which caused so much embarrassment to the crown during the Fronde and throughout the eighteenth century. The spirit that animated the *cours des aides* was very anti-fiscal; they constantly stood out against the improvements that the crown tried to introduce in the field of taxation. Men like Malesherbes (the first president of the *cours des aides* of Paris) were rather rare. Besides the *cours des aides* in Paris there were twelve in the provinces; several of these were identical with the *parlements* or *chambres des comptes* of the cities where they were situated.

AILLY; PIERRE D' (1350-1420), educator, theologian, geographer. In 1389 he became chancellor of the University of Paris, where he was the teacher of Gerson. He held positions of considerable importance in the church and in 1411 received the office of cardinal. As a theologian many of his ideas seem adventurous and even heterodox, but he desired above all else a thoroughgoing reform of the church. In the Great Schism he was the first to propose a general council which would be superior to the pope, and hoped by this means to effect a compromise which might solve the difficult problem then facing the church. At the council of Constance he put forth his views for the reform of the calendar which was finally accomplished by Gregory XIII. He is most important, however, as author of the *Imago mundi* (written in 1410, printed shortly before 1487), a summary of the geographical knowledge of the time, based on the ideas of Aristotle and Roger Bacon. It is here that one finds the first references to America. This book was attacked by many authors, but it was highly regarded by Columbus, who became acquainted with it, perhaps, even before his discoveries. D'Ailly's works comprise one hundred and seventy-four scattered monographs of varied importance.

AINGO DE EZPELETA, PEDRO. *See* EZPELETA, PEDRO AINGO DE.

AKSAKOV. Sergey Timofeyevich Aksakov (1791-1859) and his two sons Konstantin (1817-60) and Ivan (1823-86) form a triple spiritual constellation occupying an important place in the history of Russian culture. The elder Aksakov was a typical Russian country gentleman. One of the first students of the newly

founded Kazan University, he afterwards was in the government service as censor and educational official. Not until he was approaching the age of sixty did he become a writer of importance. He was not a fiction writer in the strict sense of the word, being a rare specimen of a first class artist who invented nothing but wrote about what really happened and what he himself had lived through. Hence the great, almost exceptional value of his writings as human and social documents. The classical family recollections of Sergey Aksakov give a serene and epic picture of the life of a Russian country gentleman during the later period of serfdom, in the eighteenth and early nineteenth centuries, and more particularly of that manorial colonization, hitherto very little investigated, which played such an important role in the making of Russia. The most important of his works is the famous *Family Chronicle*, of which there exist three. English translations: by "a Russian Lady" (Calcutta 1871); by J. D. Duff of Cambridge (3 vols., London 1917); and by M. C. Beverley (London 1924), with introduction by Prince Mirsky.

Konstantin Aksakov was a learned historian and philologist who, however, never did any teaching. Among the so-called Slavophiles (*q.v.*) he was the one who contributed most to the formation of their historico-philosophic doctrine in its application to the facts of Russian history. His general system of ideas shaped itself under the influence of the philosophic ideas of Schelling and Hegel. But that influence was only a passing one, and mainly formal. Having built up his Christian, semi-anarchist ideal of national and social life emancipated from the principle of coercion, Konstantin Aksakov found in the history of Russia a nearly complete fulfilment of that ideal. The essential element in his philosophy is contained in his treatment of the moral problem of social organization. Here he introduces his categories of *Bit* (customs) and *Zemlia* (country or land). *Bit* is a specifically Russian notion more or less corresponding to the German *Sitte*; it denotes the mores of a people not molded by state coercion. A community organized on the lines of *Bit* and embracing the whole nation forms the *Zemlia* which Aksakov opposes to the state. The Slavs who inhabited Russia did not "form the state out of their own midst"; they "called the state from outside" (the "calling of the Varangians," as the starting point of Russian history). The Slavs, and the Russians more particularly, are by their nature "custom"

peoples, this conception of "custom" implying in the eyes of Aksakov not only historical backwardness but a certain moral supremacy over the "state" peoples. Whereas the western nations chose the path of "external law," i.e. of "constitution" and "regulation," the Russian people, being the most Christian of all, followed and will follow the way of "conscience," of "inner truth." "The history of the Russian people is a history, unique in the whole world, of a people that is Christian not only by religion but also by its life, at least by the tendency of that life." It is surprising how Aksakov managed to combine such mystical, unhistorical idealization with an excellent first hand knowledge of the facts which enabled him as historian to utter some sound and critically fruitful judgments. Like the rest of the Slavophiles K. Aksakov believed autocracy, somehow combined with individual rights and consultative popular representation, to be the only form of government suited to the spirit and interests of the Russian people. His original approval of the reform of Peter the Great and his belief in its historical vindication and necessity changed afterwards into a vehement denial of Peter's life work, as well as of the entire "Petersburg period of Russian history" (the expression was coined by him). He regarded it as a pernicious departure from the right path for which the government and the upper classes were to blame. Thus, like all real Slavophiles, K. Aksakov was a preacher of a peculiar kind of social and ethical nationalism, being in practical politics a moderate liberal and a partisan of liberal reforms. Ivan Aksakov, who on the whole faithfully clung to the historico-philosophical and sociological ideas of his brother, regarded the latter's social ideal as in some respects akin to that of the German sociologist W. H. Riehl. The works of K. Aksakov were edited by his brother Ivan in three volumes (Moscow 1861-80); this edition remained incomplete; the first volume, containing the most important historical works, was republished in the twentieth century.

Ivan Aksakov was the practical politician of the Slavophile movement. He had in general a practical mind and great literary and oratorical gifts. At first a government official and a judge (1842-52), he afterwards became and remained a journalist, engaging in economic studies and researches whenever the conditions of censorship reduced him to silence. The significance of Ivan Aksakov lies in the fact that while sharing the ideas of mystical nationalism common to

all the Slavophiles, he yet fought for liberal reforms and was a staunch supporter of the policy of moderate liberalism. I. Aksakov exerted an especially strong influence as chairman of the Slavonic Philanthropic Committee of Moscow during the Russo-Turkish War of 1877-78; because of Aksakov's daring speech against the decisions of the Berlin Congress, the committee was later dissolved and Aksakov himself subjected to persecution. He was a champion of Russia's mission as the liberator of the Slavs from the Turkish yoke, and as such was named in some Bulgarian quarters as a candidate for the Bulgarian throne when the Bulgarian principality was created. In Russian home affairs he of all the Slavophiles was probably the most sober and the best endowed with a sense of realities. There is in the Russian language no better defense of the freedom of speech than Aksakov's brilliant writings on this subject. His letters, a classical example of Russian epistolary literature, have also a great historical documentary value. His verses on political themes give him a prominent place in the history of Russian poetry. Quite a special place in the life work of I. Aksakov is occupied by his investigation into the conditions of trade at the Ukrainian fairs, the results of which were embodied in a large monograph, *Recherches sur le commerce des marchés de l'Ukraine* (St. Petersburg 1858). This classical work of Russian descriptive political economy is full of subtle psychological observations, and among other things contains a very interesting characterization of the "Great Russian" and the "Little Russian" as psychological and economic types. The collected works of I. Aksakov consist of seven volumes (Moscow 1886-87), but that edition is not complete. Three volumes of his *Letters* were published separately (Moscow 1888-92).

ALABAMA CLAIMS. The *Alabama* claims, settlement of which constitutes an outstanding example of arbitration in a dispute of major importance, arose from the inadequate performance of neutral duties by Great Britain during the American Civil War. Confederate cruisers, equipped in British ports and later armed out-

side British jurisdiction, or whose force was augmented in British colonial ports, inflicted damages on Union commerce estimated at nearly eighteen million dollars and caused the Union navy to spend seven millions in pursuit of them.

In the North great bitterness against England prevailed on this score. Lord Russell refused arbitration in 1865 on grounds of national honor, but his successors at the Foreign Office showed a greater desire to assuage American ill will and, by setting up a higher standard of neutral obligations, a wish to protect British commerce from new *Alabamas* in the event that Great Britain should be a belligerent. The Johnson-Clarendon claims convention of January 14, 1869, contained no expression of British regret but provided for the appointment of an umpire by lot in the case of each claim as to which the commissioners disagreed, if the commissioners failed to agree on one umpire for all the cases. It was rejected by the Senate, forty-four to one, after an extravagant speech by Sumner holding England responsible for the prolongation of the war. Danger of an Anglo-Russian war in 1870, however, led to a confidential mission entrusted to Sir John Rose. This paved the way for a joint high commission which, by the Treaty of Washington, May 8, 1871, referred pending disputes to four separate arbitrations. The British expressed regret for the escape and depredations of the *Alabama* and other vessels, and agreed to refer the claims growing out of the acts of these vessels to a tribunal of five arbitrators which should meet at Geneva and should apply the following three rules, even though the British denied the American contention that these rules stated the principles of international law in force when the claims arose:

"A neutral Government is bound—

"First, to use due diligence to prevent the fitting out, arming or equipping, within its jurisdiction, of any vessel which it has reasonable ground to believe is intended to cruise or to carry on war against a Power with which it is at peace; and also to use like diligence to prevent the departure from its jurisdiction of any vessel intended to cruise or carry on war as above, such vessels having been specially adapted, in whole or in part, within such jurisdiction, to warlike use.

"Secondly, not to permit or suffer either belligerent to make use of its ports or waters as the base of naval operations against the other, or for the purpose of the renewal or augmentation

of military supplies or arms, or the recruitment of men.

"Thirdly, to exercise due diligence in its own ports and waters, and, as to all persons within its jurisdiction, to prevent any violation of the foregoing obligations and duties."

Inclusion in the American case of indirect claims arising from the transfer of American shipping to British registry enhanced insurance premiums, and the prolongation of the war was apparently designed to obtain the rejection of such claims by the tribunal and thus to protect the United States, when neutral, from similar pretensions. As the British held that such claims were barred by the treaty, the tribunal saved the arbitration from imminent shipwreck by excluding the indirect claims from consideration. On September 14, 1872, by a majority of four to one, the tribunal awarded the United States \$15,500,000, including interest, for losses caused by the *Alabama*, the *Florida* and their tenders, and by the *Shenandoah* after her force was augmented at Melbourne. Judgment was in favor of Great Britain in the other cases. Costs of pursuit were excluded as not properly distinguishable from the general expenses of the war.

The decision, however, that "'due diligence' . . . ought to be exercised by neutral governments in exact proportion to the risks to which either of the belligerents may be exposed, from a failure to fulfil the obligations of neutrality on their part," is believed to be a vague and unsatisfactory measure of neutral obligation. It is to be noted that the Hague Rules of 1907, while recognizing the first rule of the Treaty of Washington as expressing a general principle of international law, substituted for the obligation of "due diligence" the duty of employing "the means at its disposal."

Thus the *Alabama* claims served to crystallize a much discussed problem in international law as to the duty of neutrals in preventing not only the outfitting but the building of armed vessels or vessels of war. The subject was of small importance in the days when only small sailing vessels were built and used for naval warfare. The destructiveness of a modern war vessel, however, is so great that it may prove a decisive factor; moreover its sale by a neutral is more readily recognized as an unfriendly act.

ALBERDI, JUAN BAUTISTA (1810-84), Argentine political scientist, sociologist, economist and lawyer. He studied in the University of Buenos Aires and received his doctorate in law from the University of Córdoba in 1838. He joined with Echeverría, Miguel Cané the elder and J. M. Gutiérrez in opposition to the dictatorship of Juan Manuel de Rosas and was forced to emigrate to Montevideo (1839), where he continued his propaganda, and thence to Chile, where he developed a reputation for his legal learning and his journalistic efforts. Upon the fall of Rosas (1852) he composed in five days *Las bases*, the best known of his works, an analysis of liberal American constitutions, with recommendations for the new Argentine constitution, which he anticipated. Most of his suggestions were adopted and he became adviser to the new Argentine president, Urquiza, who sent him on a diplomatic mission to England, Spain, France and the Holy See. When Urquiza's confederation was overthrown in 1861 by political combinations in Buenos Aires headed by Mitre and Sarmiento, Alberdi remained in Europe. He died in Paris, a virtual exile. His works on social subjects totaled twenty-four volumes, sixteen of which were published posthumously. His long residence in Europe, in contact with leading minds, made him the most competent of the Argentine social scientists of his day, while his ability and liberalism made him the idol of the generation of political thinkers that followed him.

ALBERONI, JULIO (1664-1752), a cardinal and prime minister of Spain from 1715 to 1720. He was born of poor parents in the duchy of Parma, and after entering the priesthood rose rapidly to prominence. Alberoni was introduced to the court of Philip V through the French general, Marshal Vendôme, at the time when French dominance in Spanish councils was being maintained through the influence of the celebrated Madame des Ursins. Alberoni successfully induced her to sponsor the marriage of Philip V to Elizabeth Farnese (Isabel Farnesio), who later earned her title, the "Termagant of Spain." Backed by the determined queen, Alberoni managed to become head of the ministry and from that position was eventually elevated to the rank of cardinal.

He found Spain at the lowest ebb of her political fortunes, but he was so competent an executive that under his administration Spain became again a first rate factor in European affairs. He introduced important changes in the fiscal system, encouraged the manufacture of woollens and linens, enlarged the navy and strengthened fortifications. These internal reforms were a necessary prelude to the ambitious role which Alberoni had decided that Spain should play in Europe.

The inspiration of his foreign policy remains somewhat enigmatic, but it has been conjectured that as a patriotic Italian he hated the emperor for having made Italy the battle ground of Europe, and looked toward the aggrandizement of Spain in order that its splendor might insure the peace of Italy. He spread a remarkable net of secret intrigue in all the courts of Europe in furtherance of his plans to secure alliances for Spain. Finally, assisted by the great organizer Patiño, he sent Spanish forces to Sardinia in 1717 and to Sicily in 1718, overrunning both. This aroused a storm in Europe and produced a coalition of England, France and Austria; the kingdom of Sardinia eventually

forced Spain to yield her conquests and to dismiss her minister.

In a sense Alberoni had failed, but he had in fact started that movement of regeneration in the peninsula which was to culminate in the reign of Charles III (1759-88). In his later years he drew up plans for a Diet of Perpetual Peace, advocating a European league of the Christian nations. These ideas of one of the greatest exponents of secret diplomacy in its most exaggerated form were in their time, perhaps, not inconsistent with an ultimate objective aiming at the general pacification of Europe.

CHARLES E. CHAPMAN

Consult: Ballesteros y Beretta, Antonio, *Historia de España y su influencia en la historia universal*, vols. i-v (Barcelona 1919-) vol. v, p. 48, 118-19, which gives an extensive bibliography. R., "Cardinal Alberoni, an Italian Precursor of Pacifism and International Arbitration" in *American Journal of International Law*, vol. vii (1913) 51-82.

ALBERTI, LEON BATTISTA (1404-72), Italian humanist, born in Venice of an illustrious Florentine family. A man of universal interests, his work as an author, scientist, moralist, economist and aesthetic philosopher was distinguished by clear judgment and good taste, which also guided him in the practise of the arts of music, painting, sculpture and architecture. His life was one of industry and concentration and, possessed of a strong sense of reality, he achieved a happy equilibrium between the useful and the ideal, between scientific precision and free imagination, and between the demands of the ego and those of social consciousness.

Alberti's educational ideal differed from that of the fifteenth century, in which literary culture was considered equivalent to a knowledge of humanity (Petrarch, Vittorino, Vergerio, Veggio, Filelfo, etc.). The struggle with fate, the necessity of feeling God in his own nature, were the realities of man's existence and were far removed from the life of the man of letters, whom Alberti regarded as being a naïve child—the eternal pupil. He expressed this contrast in striking fashion in his first great satires on the literary man, the theologian and the scholar; the man of action is contrasted with the *littérateur*, and the reality of a life of activity in which the will is directed to the cultivation of virtue and of the art of life is opposed to the concept of human culture as study dependent upon erudition and

memory. He advised the aristocrat to educate his son for some occupation such as agriculture, navigation or the crafts rather than for the empty life of a literary dilettante. Life is an art, and art in this larger sense is the result of active practise. The proper direction of a family is the highest art. The perfect school is that which is directed by experts; education culminates in self-control, and the perfect society is the society of the self-controlled.

ALBERTUS MAGNUS (1206-80), theologian and philosopher. While his father, a powerful feudal noble, was at war with Lombardy he was sent to study at Padua, where he joined the Dominican order (1223). He studied and taught theology at Cologne and at various Dominican monasteries, and in 1245 went to Paris to occupy one of the Dominican chairs in theology. Thomas Aquinas studied under him at Paris and returned with him to Cologne (1248), where Albertus was to establish a *studium generale*. Together with Aquinas and Peter of Tarentasia he drew up the regulations governing studies in the Dominican order (1259). He was made bishop of Ratisbon (1260-62), accepting the post against his wishes in order to indicate his obedience, and resigning it after having shown his incapacity for a decent period. After the death of Thomas Aquinas he traveled to Paris to defend the doctrines of Thomas from the attacks of the bishop and the clergy (1277).

Albertus' project was to write a work for every work Aristotle had written or had planned. The completion of that encyclopaedic task introduced to western Europe for the first time a body of positivistic knowledge modeled on the sciences of the Greeks. In the course of his labors Albertus wrote an *Ethics* and a

Politics which made readily available the social theory of Aristotle, and reenforced with a body of theory the emphasis placed in Christian ethics and canon law on importance of habituation in the virtues and on consent in law. It was Thomas who synthesized and systematized the vast and diverse materials which Albertus had assimilated.

ALBUQUERQUE, AFFONSO DE (1453-1515), Portuguese soldier and statesman, founder of Portugal's Indian empire, one of the earliest advocates of commercial imperialism and of preparedness as the means to prevent war. The aim of his conquests as governor general of India (1509-15) was the Portuguese monopoly of Indian commerce. To effect this he determined to control the source of supply by occupying the principal Indian ports from Malacca westward and to prevent all Mohammedan commerce with Europe by policing the Red Sea, especially at Aden, its southern entrance. His Red Sea expedition failed, but at the time of his death Portugal was strongly entrenched in Malacca, Ormuz, Calicut, Cochin, Cannanore, Goa, and was on friendly terms with the East Indian kingdoms and with Siam, China and Java.

Since eastern commerce was almost entirely in the hands of the Mohammedans, to destroy it was also to spread the gospel. To this end Albuquerque allied himself with Hindoo princes. He appointed Hindoos to minor administrative positions and attempted to establish schools to educate them in western customs and language. Hindoo women were married to Portuguese men in a consistent attempt at permanent colonization. Albuquerque was not deficient in cruelty yet he prohibited suttee in the island of Goa; and he restored the original tax levy which had been doubled by a previous conqueror. The Hindoos said of him when he died "that God had need of him for some war and had therefore sent for him."

CLARA W. MAYER

ALCABALA is a turnover tax which exerted considerable influence in the economic development of Spain. It has a very long history. A successful complaint on the part of some Spanish communities against the dishonest farming out of the alcabala by the praetors is recorded as early as 171 B.C. An inscription indicates a turnover tax of one half percent in Baetica at the time of Augustus. Coimbra had a turnover tax in 734. In documents of the twelfth century the alcabala is mentioned as a community tax, corresponding to earlier regulations in Greece, Macedonia and Rome, and to a contemporary development in Germany, France and the Orient (Mecca).

Through its reintroduction in 1342 the alcabala became generally significant. The Cortes of Castile in Burgos and the Cortes of León granted it to Alfonso XI (1312-50) in the form of a 5 percent tax on all goods in Castile and León, i.e. on all business turnovers, from producer to consumer, on condition that it be in force only during the siege of Tarifa and Algeciras. The alcabala retained its character as both war tax and special tax during the fourteenth century, as is evidenced in the levy by the Cortes of Alcala for the siege of Gibraltar (1349). Beginning with 1366 the tax rate was 10 percent, and after a temporary reduction it rose to the same amount under Ferdinand V and Isabella of Castile (1474-1516) and under Philip II (1556-98). The Spaniards began to introduce the alcabala into the kingdom of Naples and into their American colonies in 1558. An attempt to introduce it into the Netherlands, however, met with failure in 1571.

Philip IV increased the rate on the last turnover by 1 percent successively in 1642, 1656 and 1664; henceforth until about 1785 the rate was 11 percent for the retail trade, the charge on other business turnovers remaining at 10 percent. From 1785 on, the general rate on the necessities of life was lowered to 2 percent; moreover the tax was made payable only for the first sale, all subsequent transfers being made free of tax. The alcabala acquired thus the character of a production tax.

To avoid the difficulties of administration the

kings made tax agreements (*encabezamiento*) with the communities (1494, 1509, 1513, 1537, 1556), according to which the latter had to pay in each case stipulated lump sums that were raised by means of the alcabala administered by them. The amount payable to the king was calculated in such a way that the actual total burden of the alcabala, making allowances for exemptions, did not amount to more than 5 percent. Owing to laxity in administration the yield declined to 2 or 3 percent, but the administration improved and the yield increased under Philip II. This caused the cities to oppose the *encabezamiento* procedure. Charles V attempted to avoid this difficulty first by abolishing this method of collection, then by extending it to all taxes and in 1523 by substituting a head tax for the alcabala. The ensuing changes in the amounts payable to the king produced a total tax burden of 7 percent from 1562 to 1576, 20 percent from 1576 to 1584, 15 percent from 1584 to 1595, and 7 percent again in 1620 and afterwards.

As a rule the payment of the tax was shared equally by sellers and buyers. Confirmation by oath of the accuracy of tax statements was sometimes demanded and severe penalties were imposed for inaccurate statements, fraudulent bookkeeping or tardy payments. At first there were no exemptions, but later certain classes of persons and the sale of certain types of commodities were exempted. The persons exempted included the king and his household, many of his artisans, certain monasteries, castles and settlements, officers of the Inquisition, the nobility and some others. Except in connection with purely business transactions, the clergy were exempted. Certain prelates enjoyed the same privilege in selling the products of their orders' benefices. Transactions in saddle animals, books, manuscripts, paintings, hawks and other hunting birds, slaves imported from Moorish territory in war time, cattle, weapons, certain cloths, bread, money, wedding presents, legacies, fir wood for the royal wharves in Seville were all exempted.

The economic disadvantages of the alcabala were reflected in the acuteness of the conflicts over the rate and the lump sum agreements. They were accentuated by the nature of the exemptions and by the system of farming out the taxes, which allowed the tax farmer far reaching authority and which lasted, with interruptions, until 1747. There were numerous attempts at reform. So important had the problem become

that Queen Isabella in her will ordered a commission, which, however, was never created, to investigate the legality of the alcabala. In the eighteenth century the opposition was active in the textile industry in particular, but it was also carried on by individuals (as in the memorandum of Don Miguel de Zabala to Philip V in 1734). It was difficult to dispense with the alcabala; even although inefficiently administered it was a highly productive tax, so that the decrease in revenue resulting from its abolition could scarcely be compensated by other taxes. The radical changes of 1785 foreshadowed the final abolition of the alcabala by the decree of June 20, 1843, and, after its temporary reintroduction, by the federal law of May 23, 1845. The name is retained today only in connection with special transfer taxes such as the tax on real estate.

It has been thought that the alcabala retarded and inconvenienced trade and restricted production for distant markets, and it has been considered the cause of the ruin of manufactures in Spain. Some writers, especially in the eighteenth century, have even maintained that the alcabala was the sole or principal cause of the downfall of Spain. However, for lack of sufficient evidence one would hesitate to ascribe this event to any single cause. Economic greatness is a function of too many variables—political, cultural, technological—to be so completely affected and determined by a single feature of governmental policy.

ALCHEMY. An art of solitary adepts working in secret under the lure of great personal gain, alchemy has always remained in a stage of uncertainty and suggests the somewhat confused mental attitude of the would-be inventor who has not yet succeeded in working out his idea and making it practical. At various times and places it has been illegal, or at least the object of hostile legislation and moral criticism. If it did not originate in, it has been associated

with, the fraudulent practises of workers in metal, the making of imitation or artificial gems, counterfeiting, medical quackery and the magic arts (for specific illustrations of magic in alchemy see L. Thorndike, *History of Magic and Experimental Science*, 2 vols., New York 1923). At the same time it has closely accompanied the social service rendered by medicine and technology, and has antedated modern chemistry. It has not merely been a social fact with which we must reckon through a long period of history; it is still extensively practised and credited in Egypt and the Near and Far East.

Alchemy finds its place in intellectual history as a delusion, more learned and technical than popular, based upon or enveloping the fact, imperfectly apprehended, of chemical change. With this sound foundation and scientific center of interest, alchemy could not go wholly wrong in its aberrations or fail to stumble occasionally upon new facts of nature or useful processes. The modern scientific laboratory is in no small measure an outgrowth of the mediaeval alchemist's workshop. Because of this element of truth and the rational purposiveness and practical character of much of alchemy's procedure, such as distillation and sublimation, one hesitates to classify it as an occult science or form of superstition. But when the alchemist takes pen in hand, he is likely to begin with as large promises and startling announcements as a circus poster, to continue as fluently as a longwinded preacher, only to terminate in cryptic and enigmatic evasions. He often employs religious phraseology and reasoning, alludes to initiations and mysteries, makes much use of allegory and symbolism. On the other hand it is hard to draw any fast line between the recipes of alchemy and those of the arts, since they are found in the same treatises and authors. Alchemical theory had relations with philosophy and perhaps originated in the discussion of world grounds and the constitution of matter by the early Greek thinkers. Mediaeval alchemists related their argumentation to the philosophy of Aristotle, with further touches of neo-Platonism, mysticism and especially the astrological hypothesis that things terrestrial are governed by things celestial. Perhaps the earliest explicit association of seven metals with the planets is in the account of Persian Mithraism by Celsus, the second century foe of Christianity (see Origen, "Reply to Celsus,"

in *Ante-Nicene Fathers*, 10 vols., Buffalo 1887-96, vol. iv, p. 583).

The earliest extant alchemical writings, however, are in Greek from about the third to the fifth century. Zosimus was alchemist as well as historian. The authors of these treatises regard their art as descended from ancient Egyptian kings and priests, and there are other reasons for tracing alchemy back to Egypt or for assuming a strong influence of Egyptian thought and ritual upon alchemy, perhaps indirectly through gnosticism. A recent Greek writer has placed the birth of alchemy rather late in Egyptian history, at 718 B.C. during the Ethiopian invasions (see M. Stephanides, "La naissance de la chimie" in *Scientia*, vol. xxxi, 1922, 189-97). But Julius Ruska, in a still more recent detailed study of the Emerald Table ascribed to Hermes Trismegistus, finds signs of a strong Persian influence.

Although alchemical writings in Greek run into the Byzantine period, and technical recipes in Latin continue in unbroken tradition through the early Middle Ages, it was especially by translation of works in Arabic that alchemy spread in western Europe from the twelfth century on. Berthelot regarded Arabic alchemy as fantastic and magical compared to later mediaeval works in Latin. But the recent investigations by such scholars as E. Wiedemann, E. Darmstaedter, H. E. Stapleton and E. J. Holmyard in Arabic manuscripts and sources have rehabilitated Jabir ibn Hayyan as one of the greatest figures in the history of alchemy, and brought out the positive experimental contribution of Arabic alchemy.

The generalization may nevertheless be hazarded that alchemy grows less magical and more scientific as we advance through mediaeval to modern times. The use of minerals, metals and chemicals in medicine may be traced back earlier than Paracelsus and the iatrochemists of the sixteenth and seventeenth centuries. Learned men such as Conring, Libavius, Ashmole and Sir Hans Sloane, founder of the British Museum in 1753, and even such scientists as Stahl and Boyle, retained faith or at least interest in the possibility of transmutation.

This was a speculative or scientific interest rather than a craving for lucre. Possibly the scarcity of capital before modern times may have motivated the activities of alchemists, but success on their part is seldom recognized in past literature outside of their own propaganda. Diocletian is said to have burned the books of

the alchemists in Egypt because their activity had financed revolts against him, but one recalls more allusions to persons who lost their gold by employing alchemists in the effort to multiply it. In the fourteenth century the inquisitor Eymeric declared that alchemists come under the censure of divine law as intent on gold, and accused them of defrauding even the poor. On the other hand both Franciscan friars and Rhenish archbishops are listed prominently among devotees of the art.

ALCIATI, ANDREA (1492-1550), Italian jurist, who played a leading part in the revival of the study of Roman law and in the reestablishment of its authentic texts during the humanist movement of the sixteenth century. He held successive chairs of law at various Italian and French universities, wandering to

and fro at the invitation of sovereigns or as a result of local strife and the tumults of war. His lectures drew large audiences, including distinguished scholars and aspiring social and religious reformers from many countries; his numerous writings soon exercised a profound influence on the development of legal science in Europe. He was in constant touch with the general reform and renaissance movement, and was closely associated with such men as Erasmus, Bembo, Sir Thomas More, Zasius, John Calvin, Theodore Beza, Vasari and J. Amyot. He admired Luther's ardent courage, but deplored his invective and rough manners. He never abandoned Catholicism, though he disapproved of the license at the papal court, superstitious belief and any violent assertion of authority.

Alciati's works, which are inevitably fragmentary, represent the lifelong strivings of a keen explorer, the critical views of an untiring controversialist, and the reconstructive conceptions of one who sought to separate the true from the false (which had been mixed up for centuries), the trivial and irrelevant from the significant and material. His aim throughout was to show the real meaning and application of the Roman law, and to liberate it from its destructive incubus of spurious additions and erroneous interpretations by preceding glossators and commentators: that is to say, his purpose was not merely analytical and expository, but—what was of supreme importance then—historical and comparative, based on the true original sources.

As a humanist he held, contrary to many contemporary jurists, that he who would be a sound lawyer should not limit himself to the study of law but should devote himself also to history, literature, philology, political science and other ancillary subjects. In the search for truth he set knowledge and independence of thought over against unreasoning tradition and dogmatic authority; and he regarded a jurist as a priest in the service of justice. He is a founder of the scientific method in jurisprudence, and to him is due the rise of the great French school of law in the sixteenth century.

ALCOHOL.

HISTORICAL ASPECTS. Alcohol has been used by mankind since the remotest antiquity, and its use has extended over virtually all parts of the earth. Its principal significance for the history of culture arises from its use as a beverage.

It is convenient and customary to classify alcoholic drinks as beers, wines and distilled liquors. Beer is produced by the fermentation, aided or unaided, of grains or roots. Virtually every cultivated cereal known to man, and many roots, appear to have been in use for beer making. To judge from its distribution, the making of beer may be considered to have originated relatively early among some agricultural group of the Old World and to have spread throughout the agricultural cultures of the Old World and most of those of the New World. Non-agricultural hunters, mere gatherers of wild grains and roots, such as the wild rice gatherers of the Great Lakes region of North America, the root gatherers of northwestern North America and the aboriginal Australians, have no knowledge of beer making. The agriculturists of North America, save in the Pueblo region of the Southwest of the United States, had no knowledge of beer; neither, apparently, had the agricultural Melanesians and Polynesians.

The problem concerning the appearance of beer making in America has not yet been settled, although the idea of diffusion is strongly supported by the distribution in America, Oceania and southeastern Asia of the masticatory preparation of beer and kava (the latter a non-alcoholic drink). Mastication of starchy grains and roots through the action of the saliva facilitates the conversion of the starch into sugar, and consequently hastens the fermentation. In Formosa and southeastern Asia rice flour is masticated by women in the preparation of rice beer. In Polynesia (but not Melanesia) the pepper root is masticated in preparation of kava by both men and women. The saliva aids in releasing the active alkaloid. Throughout the range of maize and manioc culture in the Americas, except in non-Puebloan United States, maize flour or manioc root is masticated by women in preparation of maize or manioc beer. In Mexico peyote was thus masticated in the preparation of a non-alcoholic beverage. This and kava preparation are perhaps interesting examples of a process taken from one complex and transferred to another.

Wines are the fermented juices of stems (such as sugar cane and palms), of fruits (such as the

grape), of flowers or of berries. Mead—fermented honey—may be classed as a wine, and also kumiss—fermented milk. Grape wine is peculiar to the grape growing region surrounding the Mediterranean. Palm wine is universal in agricultural Africa, around the Indian Ocean littoral, and in the agricultural Americas except north of Mexico. In Mexico sap from the flower stalk of the agave (century plant, or aloe) was used to make wine (pulque). Mead and kumiss appear to be correlated in distribution and may be presumed to have originated among the pastoral peoples of the central Eurasian plains. Both of these aberrant forms of wine were used throughout Europe (even in Iceland and Lapland) and western and central Asia; and among the Kaffirs of South Africa (to whom they spread, no doubt, with cattle domestication). The Chinese, Japanese and southeast Asiatics will not use milk or milk products and consequently have never adopted kumiss. Non-agricultural and non-pastoral races do not use wild berries or fruits for wine making, and all forms of wine may be considered to be, with beer, originations of some agricultural people.

The history of distillation is very obscure. From the available data it may tentatively be considered to have been invented for non-beverage purposes by the alchemists shortly before our era and then applied to the distillation of wines and beers. Distillation was perhaps first used to produce distilled alcoholic beverages in India about the beginning of our era; it spread thence throughout Europe and Asia in the first millennium of our era, and in the second half became world wide; it spread even to primitive peoples such as the North American Indians, who had previously not known even wine or beer. Thus it appears that the use of beers and wines is correlated with the distribution of advanced primitive culture; and the distribution of distilled liquor is correlated with higher civilization and its spread.

One might expect to perceive in history evidence of physical and cultural disintegration, at least among groups where there has been widespread use of governmentally uncontrolled and therefore imperfectly performed distillation of strong liquors. But even in the case of mediaeval Japan (*cf.* Morewood) and of Ireland and Scotland of the past several centuries, where there was such a widespread use of badly distilled illicit whiskey, we witness the development of populations of more than average health and physical vigor. In contrast to the

peoples just mentioned we witness in history the physical and cultural recession of the Hindoo and Moslem peoples who have measurably reduced alcohol consumption through prohibitory legislation. However, conclusions from history as to the racial benefits of alcoholic consumption are difficult to draw.

Social history evidences repeated opposition on the part of the organs of social control of various groups to the abuse of alcoholic beverages. Usually the opposition to their abuse has led to their prohibition. And it is a striking fact that, until the recent prohibition in Russia and the United States, all prohibitory legislation has been among wine drinking nations. It is furthermore a striking fact that all prohibition has been a failure, the effect having been only to increase social hypocrisy and to augment the use of liquors distilled without governmental supervision or commercial standardization and therefore containing poisonous by-products of imperfect distillation, with consequent menace to the public health.

Hindooes have been forbidden the use of alcoholic beverages since late Vedic times. In the later *Smritis* the manufacture, transportation, giving, sale, acceptance or use of any alcoholic beverages was a capital offense. The laws of Manu required suicide of any Brahman touching liquor. Even using a wine bottle for water was a sin and a penal offense. Hindoo prohibition for two thousand years has been ignored by the lower classes and only nominally obeyed by the upper classes. Even the Brahmans have always drunk secretly. Breath purifiers were and are used to conceal the universal hypocrisy. Some important Hindoo cults even drink openly, but before drinking they recite a formula over the liquor to secure advance absolution for the sin of drinking it.

Mohammed forbade all use of alcoholic beverages to all Moslems, but alcohol has been stronger than the Koran and, save for several small fanatical sects, all Moslems have drunk, some openly, some secretly, some moderately, some to excess.

The Aztec cities of ancient Mexico had prohibition laws which permitted the use of alcoholic beverages only to the sick and aged, to hard workers in the building trades, and on festal occasions to the common people. There was much infringement of the law, but available data seem to indicate that it may have had some measure of success. In Incaic Peru there was prohibition only of the use of one particularly

intoxicating beer (the *sora*). In ancient China and the ancient Mediterranean region there were several minor sporadic attempts at prohibitory legislation, short lived and unsuccessful.

In the movements of frontiers during the modern period (since the initiation, about 1450 A.D., of the establishment of direct European contacts with the relatively primitive peoples of Africa, Oceania and America), we are able to witness the effect of the introduction of distilled liquors among peoples who previously were ignorant of them—even, like the North American Indians and Polynesians, ignorant of wines and beers. A resumé of the facts shows that the effect was initially disastrous but that the native peoples were gradually able to develop control over their appetites and moderate their consumption. The Polynesians and North American Indians, it is true, have virtually died off, but this has been due to the operation of factors which were chiefly economic; the Indians of Latin America and the Negro in Africa and America have become adjusted socially to alcohol and are increasingly vigorous and prolific.

Economically alcoholic drinks have not played a very significant role in history. Their bulk in relation to value has been such, considered along with the fact of the universal prevalence of raw materials from which they may be manufactured, that transportation costs make economically unprofitable inter-group trade in any but local specialties desired by the rich for variety's sake. As an element in consumption economically considered these drinks have been more significant, but their economic importance is reduced by the fact of their cheapness considered in relation to the cost of other foods or indulgences and in relation to the amount an individual may regularly consume. It is true that the drinks are often made costly by state taxation and the total national expenditure on them is relatively great, but much of the price paid by the consumer is then properly chargeable not to the consumption of alcohol but to contribution to the public treasury.

W. C. MACLEOD

BIOLOGICAL ASPECTS. The reasons why mankind has used alcoholic beverages so long and so universally may reasonably be presumed to be basically two in number. In age long experience mankind has found that, in general, alcoholic beverages are pleasant rather than painful in their physical and psychic effects upon the organism and useful to the physiologi-

cal (including the psychological) economy to a degree which throws the balance on this score in their favor. If in the common sense of mankind alcohol as a beverage had been found to be unpleasant, useless or necessarily and inevitably harmful, its use in this way would have ceased centuries ago.

Dodge and Benedict have pointed out that at the present time millions of people regularly obtain a somewhat larger proportion of their total energy requirement from alcohol than they do from proteins. Alcohol in moderate amounts is almost completely oxidized or burned in the human body, yielding energy available for use in muscular work and in the maintenance of body temperature. This fact, by definition, makes alcohol a food. It can within limits replace equivalent amounts of fats and carbohydrates in the diet, and within these limits can spare protein in the same way that fats and carbohydrates can. Richter, in a remarkably thorough, long continued and critical piece of research, has demonstrated that rats which took alcohol ate from 16.9 to 35.6 percent less than controls which drank pure water. In spite of the fact that they ate so much less they grew just as rapidly and reached the same body weight at maturity as the controls. Under conditions of nearly equal activity the energy of the alcohol, calculated in calories per kilogram body weight, exactly counterbalanced the decrease in energy intake. The conclusion was drawn that, in the rat, alcohol not only replaces isodynamic quantities of food in maintaining energy balance, as was demonstrated in man by Atwater and Benedict, but it is also used for growth and development.

In its normal use as distinguished from its abuse alcohol has been important sociologically in two ways. The first of these is as food. The present day nutritional habits of the populations of the wine and beer drinking countries of Europe perfectly illustrate the importance of alcohol in this respect. The second way has been as a facilitating agent to social relations between human beings. Alcohol in ordinary doses is a mild narcotic, of rapid action because it is extremely diffusible and passes easily through all animal membranes. It thus brings about quickly a diminution of function of the neural mechanisms of the highest level in the cerebral cortex. Starling has well described the resulting effects upon behavior: "The self-consciousness and preoccupation of each man with his own affairs become lessened. He is more

receptive of the moods and interests of his companions. His emotional responses are more readily aroused; the solemn man unbends, the critical becomes charitable and sympathetic, the silent man more loquacious. Each man thus not only reveals himself more to his fellows but is more ready to appreciate the merits and conversation of those around him. In a word, the use of alcohol in moderation promotes good fellowship" (*The Action of Alcohol on Man*, p. 77). The collective experience of mankind has demonstrated that such forms of behavior favor social intercourse and relations.

When alcohol is taken in excessive doses its narcotic action extends from the highest neural levels to those lower and lower. If the amount taken is sufficient the personality of the individual may become completely disorganized, and death may result from the acute toxic effects of the alcohol. In the successive stages of disorganization of the personality by alcohol, the individual tends progressively to become a nuisance and potentially a menace to society, precisely as would be the case if a similar physiological and psychological alteration were brought about by any other agent.

Although in its action on the nervous system alcohol is a narcotic, its action on the biological function of growth appears generally to be stimulating. For example, Puri showed that low concentrations of ethyl alcohol in the nutrient solutions in which barley seedlings were grown had a definite stimulating effect. Pearl and Allen found that cantaloupe seeds, soaked in solutions of ethyl alcohol up to 12 percent concentration, made better seedling growth than controls soaked in pure water. Mast and Ibara found that tadpoles in weak solutions of alcohol not only lived longer than the controls but grew much larger in the same length of time; so much so that the superiority was apparent at a glance and required no elaborate measurements for its demonstration. But these findings are of purely biological interest.

As far as man is concerned there are two aspects of the problem of the biological effects of alcohol which are of direct sociological import: first, the effect of alcohol upon longevity; and second, the racial effect of alcohol. The experience of insurance companies has long been cited as demonstrating that the use of alcoholic beverages of any amount or kind shortens the duration of life, as compared with total abstinence. This evidence, however, cannot be taken as conclusive regarding the point of real interest,

namely moderate use as contrasted with abuse, because no insurance records have made possible a distinction between moderate drinkers and heavy drinkers. An extensive and critical study of this problem has been made by Pearl, using specially collected and reliable material. The results regarding expectation of life are shown for males in the following table:

EXPECTATION OF LIFE, IN YEARS, IN THE SPECIFIED GROUPS OF MALES

AGE	ABSTAINERS	MODERATE DRINKERS	HEAVY DRINKERS
30	36.34	36.75	28.57
35	32.69	33.22	26.31
40	29.06	29.69	22.41
45	25.47	26.21	19.85
50	21.99	22.84	17.57
55	18.64	19.60	15.51
60	15.49	16.56	13.61
65	12.58	13.75	11.83
70	9.97	11.21	10.13
75	7.71	8.96	8.45
80	5.90	7.01	6.78
85	4.55	5.35	5.18
90	3.44	3.99	3.88
95	2.54	2.90	2.83

Person-years exposed to risk in the group	21,594.0	43,011.5	24,371.0
---	----------	----------	----------

The data show two things: first, that heavy drinking in this group of people, as compared with either total abstention or moderate drinking, definitely reduces the expectation of life at all ages from thirty to seventy; and second, that moderate drinking in the group studied did not reduce the expectation of life, at any age from thirty on, below that of abstainers.

When, however, both moderate and heavy drinkers in this experience were combined to form an "all drinker" class and this combined class was compared with the total abstainer class, it was found that at all ages up to seventy the death rates were higher for the drinker than for the abstainer group. This is the same thing that general insurance data show. These results again demonstrate the importance of a clear distinction between the normal moderate use of alcoholic beverages and their abuse.

The racial effect of the use of alcohol has been extensively studied. The important net results of the considerable body of careful, painstaking experimental research with lower animals which has been concerned with this problem lead to several significant conclusions. First, the racial effect of alcohol is preponderantly beneficial or, at the worst, not harmful. This is true for characters depending upon

general vigor in guinea pigs (after early generations are passed), fowls, rats, mice, rabbits, insects and probably frogs. Second, this beneficial racial effect appears to be the result primarily of the fact that alcohol acts as a definite but not too drastic selective agent upon both germ cells and developing embryos, eliminating the weak and leaving the strong. Third, there are only three racial effects of alcohol which can possibly be regarded as harmful that have yet been brought to light by this mass of experimental work. The first is the production of defective offspring in early generations by alcoholizing guinea pigs (Stockard). This result is peculiar to the guinea pig and was not found even for that animal by Pictet. No such effect has been noted in any other animal: not in the fowl (Pearl, Danforth); rat (MacDowell, Hanson); mouse (Gyllenswärd, Nice, Bluhm); rabbit (Rost and Wolf); frog (Bilski); or various insects (Pictet, Harrison, Mann). The second is a possible slight reduction in activity and ability to learn among the offspring of alcoholized white rats (MacDowell). The third is a reduction in fertility following the administration of alcohol. This, however, is one element of a selective process which ultimately is beneficial to the race.

Comparatively little critical work has yet been done on the racial effect of alcohol upon man. But the most thorough and significant investigation which has been made in this field (Polisch) shows that in a group of very heavy, steady drinkers there was not the slightest evidence of demonstrable germinal injury of the offspring.

RAYMOND PEARL

ALCOHOLISM. The problem of alcoholism arises from the results, individual and social, that follow the excessive consumption of alcoholic liquors. Its study involves an inquiry into what these results are in fact, altogether apart from what they should be according to our notions of the fitness of things.

There is a group of substances, of the methane series, which are known to chemists as alcohols. These include glycerine; most of them, however, are intoxicating and some, such as amyl alcohol, are highly dangerous to health. Of these, ethyl alcohol is the basis of all malted and distilled liquors and, along with such substances as ether, is one of the chief known intoxicants. In the Pharmacopoeia it is labeled as a poison, being a mild drug of addiction of less potency than cocaine, opium derivatives and crude opium, in the order named. The lethal

dose for a normal man is about a pint and a half of proof spirit. This harmfulness when taken in excess alcohol shares with common substances such as nicotine and table salt. Unlike these, however, alcohol is pleasant to most palates and the system has no automatic check upon excessive absorption. Although both acute and chronic alcoholic poisoning are by no means uncommon, the chief significance of alcohol is as a beverage, a food and a drug. The problem of alcoholism arises from the narcotic effect of a liquor which is pleasant as a beverage and which may have properties as a food.

The use of alcohol as a beverage is almost universal among the human race, the exceptions being a few primitive peoples such as the Andaman Islanders. The theory, however, of the late Dr. Archdall Reid that the craving for alcohol is an "instinct" has not been widely admitted. Nor have the attempts to explain alcoholism in terms of climate or of race been generally accepted. Climatic considerations will scarcely account for the heavy alcoholic consumption per capita of France, for the fact that Denmark consumed between three and four times as much liquor as Norway before the latter adopted prohibition, or for the great changes from decade to decade (apart from a climatic seasonal rate) in the amount consumed. The Committee of Fifty and others have shown that some races have heavy drinking habits and that the Jews have a universal reputation for sobriety, but immigration and change of conditions seem to modify these habits, and good authorities are of the opinion that Jewish temperance is due to cultural influences such as operate in the case of members of many religious denominations. Too much weight, then, must not be attributed to indications of climatic and racial variations.

The consumption of distilled spirits has increased rapidly since the seventeenth century. Drinking by industrial workers in connection with their employment has largely replaced the heavy but spasmodic convivial drinking of the Middle Ages. According to Shadwell (*Drink, Temperance and Legislation*, p. 24), the known consumption of distilled spirits in England has been:

YEAR	THOUSANDS OF GALS. (U.S.)
1684	633
1714	2,500
1727	4,322
1735	6,475
1751	13,200

From 1894-98 the annual per capita consumption of absolute alcohol in any form (Rowntree and Sherwell, p. 613) was:

United States	1.00 Gals. (U.S.)
United Kingdom	2.08 "
France	3.56 "

The annual per capita consumption separately for distilled spirits, wines and beer in United States gallons is given in the table below:

	YEAR	DISTILLED SPIRITS (PROOF GALS.)	WINE	BEER
United States	1875	1.50	.45	6.71
	1900-04	1.36	.47	16.94
	1905-09	1.43	.57	19.46
	1910-14	1.46	.60	20.38
United Kingdom	1871-80	1.42	.61	33.80
	1891-95	1.20	.45	35.70
	1900-04	1.25	.41	36.23
	1905-09	1.01	.32	32.90
Great Britain and Northern Ireland only	1910-13	.83	.31	32.62
	1923	.41	.37	19.96
	1926	.33	.50	21.53
	1900-04	.98	38.36	7.32
France	1905-09	.90	41.36	7.66
	1910-13	1.01	33.89	8.69
	1923	.71	44.38	8.03
	1926	.71	33.81	7.21

Source: The figures for the United States are adapted from the *Statistical Abstract of U. S. 1922*, p. 694. The English figures for the period until 1905 are adapted from the various issues of the *Statistical Abstract for the United Kingdom*. From 1905 on the figures given in the *Reports of Commissioners of Customs and Excises* were used; these apply to years beginning April 1. The data for France come from the *Annuaire statistique 1927*.

As indicated by the table, the consumption of alcohol in the United States was on the whole increasing before war time restrictions and prohibition went into force. In the United Kingdom there was for some years a trend toward reduced consumption, but this was slow until legislative restrictions were introduced after the war. Since convictions for drunkenness in Great Britain, however, have fallen more rapidly than the decrease in consumption, despite presumably increased police stringency, it would be improper to conclude that there is a direct relationship between consumption and the problem of public intoxication. At the same time the slow change in consumption between the middle of the last century and the first decade of this, in contrast with the rapid decline under post-war taxation, indicates the power of the legislature to control this problem far more rapidly than can be done by the slow change of manners. In 1834 the number of persons apprehended in London as

drunk and disorderly was 12.3 per 1000; in 1857 it was 6.9; in 1874 it was 6.5; in 1892 it was 5.2. In England and Wales in 1857-61 the number proceeded against for drunkenness was 428.5 per 100,000 of population; in 1874-78 it was 812.4; in 1899 it was 674.6. In 1905 the gross figures for convictions were 207,171; in 1913 they were 188,877, and in 1926 they were 67,126.

The physiological effects of the excessive consumption of alcohol are apparent in the mortality statistics. The deaths from alcoholism (using the word in the medical sense) in England and Wales were, in 1913, 2153 and, in 1924, 542, or, per 100,000 of estimated population, 5.8 and 1.4 respectively. In the United States (registration area), the figures are, for 1914, 3257 and, for 1924, 3153, or, per 100,000 of estimated population, 4.9 and 3.2 respectively (being in 1920, when prohibition was perhaps most effective, 1.0). Alcoholism is therefore a quite minor cause of death (much less than 1 percent of total deaths) and is chiefly significant as a probable index of excessive consumption. To these figures must probably be added those for cirrhosis of the liver. How far alcohol is a causative factor in this disease is by no means precisely known. Although many deaths are probably due to cirrhosis which are not due to alcohol, it is almost certainly the case that cirrhosis is primarily alcoholic and provides an index of the fluctuations of alcoholism. It thus corrects a certain unreliability, which is due to medical reluctance to certify death as being due to alcoholism, in the figures appearing under this heading. The number of deaths due to cirrhosis in England and Wales in 1913 was 3558 (1519 women) and, in 1924, 1609 (573 women), or, per 100,000 of estimated population, 9.6 and 4.2 respectively. The sex ratio will be noticed, women being by far the more sober sex. This fact is due presumably to cultural considerations and militates against any doctrine of inherited alcoholism, although heavy drinking among women is by no means recent (Shadwell). In the United States (registration area) there were, in 1914, 8526 deaths from cirrhosis and, in 1924, 7344, or, per 100,000 of estimated population, 13.0 and 7.4 respectively. This is also, then, a quite minor cause of death. Alcoholic degeneration of the heart, or "beer-drinker's heart," is probably another directly alcoholic disease, especially in heavy beer drinking countries such as Germany. Alcoholism is, however, a secondary cause of

death in many cases where the primary responsibility is not fastened upon it. According to the United States Census Bureau (1918) alcoholism is responsible as secondary cause in twice as many cases as when it is primary cause, and other careful calculations (Vernon) place the proportion at three times as many.

The morbidity statistics are unfortunately neither so easy of access nor so precise as the mortality figures. There is reason, however, to believe that the most serious effects of excessive drinking lie in a weakened resistance to disease rather than in actual alcoholic complaints. There is even more evidence for supposing that it has a deleterious influence upon the chances of recovery from illness. This is recognized as true in the case of syphilis and is also probably true (G. Sims Woodhead, Drolet) of tuberculosis. In the Bellevue and Allied Hospitals, New York, in 1912, 20 percent of the admittedly alcoholic cases, and 35 per cent of the non-alcoholic, had tuberculosis arrested or cured. In New York City in 1921 the death rate from nephritis and Bright's disease was heaviest among the Irish and Germans, traditionally heavy drinking groups.

Whatever is true of a normal drinking of alcohol, it is alleged that chronic alcoholism has an injurious effect upon subsequent generations. Early experiments (Ridge, Féré) showed the injurious effects of alcohol solutions on germinating animal life. The experiments of Stockard with guinea pigs confirmed these results and demonstrated that the number of survivors in the second generation was reduced and that of these an abnormal proportion was somehow defective. Excessive alcoholic doses, moreover, while encouraging the sexual and other impulsive activities, are liable to have a degenerative effect upon the sexual glands (Bertholet, Weichselbaum). These findings, along with the evidence of certain family studies (Dugdale, Mott), indicate that alcohol is a racial poison if taken in sufficient quantity. Stockard's further experiments, however, confirmed by others, especially MacDowell and Pearl, point to the conclusion, adumbrated by Pearson, that descendants of the normal specimens among those whose parents were alcoholized are physically superior to the descendants of the unalcoholized, presumably because of the elimination of less fit stocks. But this lethal and selective effect of alcohol can only operate when stronger and heavier doses of alcohol are taken than are probable in human consumption.

Perhaps more practically relevant to the problem of alcohol as a race poison is the probability that a pathological desire for alcohol or a remarkably low resistance to it is symptomatic of defective stock. Excessive drinking may cause defectiveness in the next generation (Kerr, Combemale, Mott), and a vicious biological circle seems to be set up, as a result of which this defectiveness itself is symptomatized by alcoholic excess.

The psychological effects of alcoholism, as shown in insanity, seem to be entirely consistent with the above hypothesis. The work of Sullivan and Mott has tended to discredit the view that alcoholism is a cause of any extensive amount of certifiable insanity, but to confirm the opinion that inebriety is one of the ways in which inferior stock proclaims itself. But if we include the earlier stages of mental defectiveness, then, as Sullivan himself says, "alcoholism is a very important cause of insanity." Persons of this kind, whether neurotics because drunkards or drunkards because neurotics, will tend to endeavor to obtain drink whenever obtainable and of whatever quality obtainable. Hence imperfectly enforced prohibition seems to have a selective and adverse influence upon them. The observations of Pollock and Furbush show that in the civil state hospitals of New York in 1912, 565 new cases of alcoholic insanity were admitted (131 females); in 1920 there were 122 cases (32 females); in 1922 there were 225 cases (32 females).

A deep seated if not inherited tendency to drink alcohol for its peculiar properties can be found in many persons who are neither drunkards nor defectives. The theory of an alcoholic diathesis, or similar theories to the effect that the individual craves alcohol to supply a deficiency of euphoric substances in the blood or glandular system or to compensate a lack of "endocrine balance" (Campbell, Crichton Miller, Berman), cannot yet be taken as generally accepted. But even if there is not a physiological basis for the craving, it may well be suggested that the psychological craving has determinable causes. According to the Freudian school this is to be found in repressed homosexuality. While admitting the intimate connection between alcoholism and release from sexual (as well as other) repressions, it seems more consistent with experience to substitute for this dogma the explanation that alcoholism is a method of finding refuge from strain. Except among defectives, alcoholic excess is probably specifically

associated with a sense of inferiority, which is allayed by the heightening of the impulsive functions in distinction to the more Hamlet-like sensitive and critical functions. Hence it has perhaps a peculiar attraction for the more introspective races (McDougall); the Negro, even if he drinks convivially and dangerously, is seldom a chronic alcoholic (Committee of Fifty). If we examine the distinct types of drinking we discover that there are roughly four. First, "misery-drinking," for which a sense of inferiority or of being unequal to the demands of the external world is responsible, although wretched economic and social conditions may often provide only the predisposing cause and personal afflictions the stimulant cause (Pringle, Kelynak). "The quickest way out of Manchester is the gin-shop." This type of drinking goes with low wages, cheap spirits and a desire for complete intoxication. Second, "industrial drinking," due partly to undernourishment but chiefly to fatigue and heat, consistent with "soaking" rather than drunkenness, and due to a desire to drink something with sufficient "kick" in it to make one equal to the task in hand. Third, "occupational drinking," where success in a trade depends upon "treating" the would-be customer or the fellow worker. In so far as it is not genuinely convivial, of all forms of drinking this seems to be the most artificial and the most easily restricted by legislation such as the British "no-treating" order. In this and the previous case occupational statistics (Dublin, Lewinski-Corwin) are of great value in throwing light upon the problem. Fourth, "convivial drinking," where there is no particular desire to become unconscious. This type of drinking conduces rather to drunkenness than to chronic alcoholism. Thus the English mining countries head the list for convictions for drunkenness, but miners are low in the statistics of mortality from alcoholism. On the other hand, at the present time, of the five economic classes in the British mortality returns, the two richest classes have the worst record of deaths from alcoholism, being able to afford the liquor. In certain circles a sense of social superiority is given by having a well filled cellar and a taste in wines of good vintage. In convivial drinking, on the whole, one notes a desire to be equal to an occasion, to secure artificially a sense of vitality which one does not possess innately, and to rise above minor worries and anxiety. Alcohol is distinctly a fear dispeller and, as a

narcotic, results in boldness of decision. Hence its use in emergencies of public speaking or social events. As Kraepelin says, its drug uses may enable morbid inhibitions to be overcome when quick decisions are needed.

Excessive consumption, to which those who stand most in need of alcohol are most tempted, may have serious social consequences stretching beyond considerations of health. Here drunkenness must probably be sharply distinguished from chronic alcoholism. In its elaborate study a generation ago the Committee of Fifty found, among 13,402 convicts, that intemperance was directly responsible for the crime in 16.87 percent of the cases, a primary cause in 31.2 percent and a factor (including herein the intemperance of others, parents or associates) in 49.9 percent. There is undoubtedly an association of drunkenness with brawls (Corradini), and also with destruction of property, assaults upon women, and solicitation of women, unwilling and willing (although there is, on the other hand, at least as much evidence that the successful prostitute is abstemious as that she is a drunkard). But skilled crimes require a steady hand. Even of crimes of violence the English figures do not fluctuate with the figures of liquor consumption (Shadwell). The more recent survey of Sullivan leads him to the conclusion that simple drunkenness is "rarely a cause of serious crime," except in connection with the sexual instinct. On the other hand, of 220 attempted suicides he attributes 78 percent to alcoholism, four fifths of the cases supervening upon chronic alcoholism. Of 200 convicts guilty of homicide, Sullivan found the act in 60 percent of the cases to be due to alcoholism; in matters of a less serious nature, especially aggravated assaults, this was the cause in 82 percent of the cases. In both groups the alcoholism was to some degree chronic. There is little proof that alcoholism has any relation to drug addiction, save that both are neurotic symptoms; restriction from the one has not been shown to lead to an increase of the other, nor yet the one to conduce to the other. In brief, the peculiar mental condition of the chronic alcoholic leads to a rather small number of offenses but these of an exceedingly serious nature (Crothers, Sullivan). It is important to add that one of the consequences of alcoholism is jealousy and a tendency to assault those with whom one is sexually related, chronic alcoholism conducing also to offenses of a perverted nature. In this connection those best

competent to judge consider as a significant index of the secondary consequences attributable to alcoholism the fact that the number of divorces granted in certain states on the ground of drunkenness has declined in direct ratio with the decline in consumption of alcoholic liquors. For the period 1887-1906 the average of the percent of divorces due to alcoholism was 3.9; in 1922 the percent was 1.0 and in 1925 it was 1.4.

The worst effects of alcoholism fall probably upon the other members of the family who do not enjoy the alcoholic euphoria. The connection between intemperance and poverty and dependence has always been recognized. For many reasons the statistics are not of a strictly scientific nature. The Committee of Fifty attributed 25 percent of the cases for relief which came within the purview of the charity organization societies to the use of alcoholic liquor, 18 percent being due to its personal use. Of cases in almshouses and workhouses 37 percent owed their dependency to intemperance and 32 percent to personal use (12.7 percent of women owing their position to the habits of others as against 6 percent of men). Of the destitution of children 45 percent was attributed to the drinking habits of others. Comparison of city with city and the previous investigation of the Massachusetts Bureau of Labor confirm these figures. Charles Booth, in his survey of East London, attributed pauperism to intemperance in 14 percent of cases, but declared it to be "the most prolific of all causes" (and the least necessary) because without it the major causes—sickness and old age—could be better met. In 1916 intemperance (with a careful definition) was found to be a cause of poverty in 18 percent of cases by the Philadelphia Charity Organization Society; the New York Charity Organization Society placed the figure at 20 percent, the Hartford, Connecticut, agency at 24 percent, and the Portland, Maine, agency, as a major cause, at 30 percent (*The Prohibition Situation*, p. 18-19). If drink is a cause of poverty, the question remains how far bad economic conditions are in turn a cause of "misery drinking" and "industrial drinking."

In the case of juvenile delinquency, although the juvenile usually becomes a delinquent before he has had time to become a heavy drinker, most social workers assert as an important factor in this delinquency the effect of intemperance in the home, although here again we may be confronted with the problem of neurotic stock. It has been demonstrated

by numerous physiological and industrial experiments that alcohol is not a thing to work on; the extent, however, of the decrease in industrial efficiency must depend upon such considerations as the time when the liquor is consumed, and the nature of the work, such as heavy routine work, on the one hand, or automobile driving, on the other. Investigations by Vernon have tended to show that the percentage of industrial accidents among munition workers was at its maximum when the chance of the recent consumption of an alcoholic beverage was at maximum. The statistics for certain British cities show a maximum of general accidents in the hours immediately following closing time on Saturday nights. The most satisfactory test, however, of the effect of drinking upon economic efficiency lies in the considered opinions of those most closely in touch with industrial conditions—the employers and workmen. In reply to a carefully worded and non-tendential questionnaire sent out by Herman Feldman, out of 175 firms replying on the subject of the individual productivity of the worker 101 stated that there was an increase due to prohibition, 3 affirmed that there was a decrease; of 223 firms answering on industrial accidents 74 claimed a reduction due to prohibition, none an increase; of 287 answering on attendance on Monday and the day after pay-day 184 notified an improvement attributed to prohibition and only 9 stated that the situation had become worse. It is affirmed by representative union officials that restriction of consumption increases the clear-headedness and disposition for initiative of the worker, and offers an escape from the vicious circle of the social consequences of alcoholism (in the sense not of intoxication but of bondage to an incapacitating habit). The shutting of the saloon, however, has left unsolved the problem of where the workers' impulse for sociability may be satisfied. The movies, which have benefited by the closing of the saloon (Feldman), have also been perhaps one of the major factors making for sobriety, since these theaters almost certainly offer a far better substitute for the saloon than the museums or libraries commended by Rowntree and Sherwell.

In summary it may be said that the problem of alcoholism is primarily the problem of a narcotic, and hence a psychological problem to which depressing environmental conditions predispose, as well as conditions of strain or conditions, physiological or social, which leave

the individual with a sense of inadequacy or deficient vitality. It may be urged that alcohol is especially deleterious in two types of cases: the economically depressed, for whom there is an external predisposing cause; and the neuropathic. The difficulty with the first could be mitigated by ownership of drinking places by the state or by public trusts, designed to remove the more obvious abuses, to encourage the drinking of alcohol only dilute and on a full stomach, not continuously, and to prevent the undue pushing of sales. It can be met more effectively (*cf.* the English figures of drunkenness convictions, *supra*) by heavy taxation, provided there be no objection to what is in effect class legislation; or by prohibition, where this is effective for both rich and poor so far as the availability of drinkable liquor is concerned. The second difficulty can in part be met by a satisfactory organization of inebriate homes and by an effective system of personal license, or by similar temperance legislation. It may be urged that alcohol is beneficial in certain emergency cases; for persons of a physiological or psychological defect of constitution (potential heavy drinkers though these be); and in the interests of conviviality. In most instances the right of medical prescription and the availability of light wines and beers could meet these difficulties. It must be remembered, however, that the effective enforcement of "light wines and beer" legislation, with a human nature which is easily incited to demand something with a "kick" in it, presents almost as many difficulties as prohibition. At least it may be said that, whatever may be the future trend of legislation, its effectiveness and permanence will depend upon its taking into consideration the local social conditions and scientific considerations of human physiology and psychology.

ALCOTT, AMOS BRONSON (1799-1888), educator and author. He was the son of a farmer and mechanic and had no formal education. In 1814 he began to earn his living in a clock factory at Plymouth, Connecticut, and afterwards traveled for many years as a peddler, chiefly in the South. He began to teach in 1823 and conducted schools at Bristol and Cheshire, Connecticut, and at Germantown and Philadelphia in Pennsylvania. In 1834 he opened the famous school in Boston where he developed his original methods of self-instruction with the purpose of stimulating the personalities of the children. He was obliged, as a result of financial failure, to abandon this enterprise in 1839, although he had originated methods that were to be adopted by subsequent generations and that are admirably described in Miss Elizabeth P. Peabody's *Record of Mr. Alcott's School* (Boston 1835). He had been one of the founders of, and chief contributors to, *The Dial* and was intimately associated with the group of transcendentalists, whose ideas he spent his life disseminating. In 1840 he settled in Concord, Massachusetts, as the friend and neighbor of Emerson and Thoreau. After visiting England in 1842 he founded the communistic enterprise of "Fruitlands" at Harvard, Massachusetts,

an attempt to combine farming and spiritual development under ideal conditions. The experiment, however, resulted in almost immediate failure. He lived for the rest of his life in Concord, and traveled throughout the country, conducting the "Conversations" for which he became famous—informal talks on a wide range of practical and spiritual topics, emphasizing the ideas of the transcendentalists.

As a thinker he was an imitator and paler counterpart of Emerson, but his philosophy never crystallized into any concrete form. His old age was brightened by the fame and financial success of his daughter Louisa, and he became in 1879 the nominal head of the Concord School of Philosophy. He was an active abolitionist.

ALCUIN (735-804), theologian and educator. He was trained at the cathedral school at York, then famous for its teachers and its library. In 780 the superintendence of the York library and school was entrusted to him. Two years later he was persuaded by Charlemagne to go to Aix-la-Chapelle and take over the direction of the palace school. Save for two brief visits to England, Alcuin remained in the Frankish kingdom until his death. In 796 he was presented with the great monastery of St. Martin at Tours, where he passed the last eight years of his life.

His numerous writings, consisting of letters, commentaries on the Bible, theological tractates, educational treatises and a considerable body of poetry, show that Alcuin had read extensively, but do not display great originality of thought. He defended the orthodox view against the adoptionist heresy preached by the bishops of Toledo (Elipandus) and Urgel (Felix). In the question concerning the relations between the temporal power and the church, Alcuin's views seem from his correspondence to coincide with those of Jonas of Orléans and of the pseudo-Isidorian Decretals, namely that the church may claim authority over all its members, including

those in whom the chief temporal power is vested.

Alcuin's chief fame rests on his work as a teacher and as Charlemagne's informal minister of education. He made the palace school and later the school at Tours the foremost in the kingdom. He inspired many of Charlemagne's decrees, which contributed much toward the establishment of an educational system and the creation of an educated clergy. Finally, according to an undisputed tradition, he supervised the much needed revision of the Vulgate.

M. L. W. LAISTNER

ALDRICH, NELSON WILMARTH (1841-1915), American party leader, known chiefly as a staunch defender of the Republican policy of protectionism and as an advocate of banking reforms. He was senator from Rhode Island from 1881 to 1911, and his own extensive investments in banking, sugar, rubber, traction, gas and electricity made him in popular fancy the representative par excellence of the big business point of view in Congress. The rotten borough system in Rhode Island enabled him to disregard the popular currents of the day without concern for his own reelection.

From 1897 until 1905 he was the leader of the inner ring which virtually dominated the affairs of the Senate. His genius as a parliamentarian and his skill in handling men extended his influence over a much longer period. He was an important factor in the framing of the following measures: the tariff acts of 1890, 1894, 1897 and 1909, the Gold Standard Act of 1900, and the Aldrich-Vreeland Currency Act of 1908.

His chief constructive contribution is in the field of banking and currency reform. As head of the National Monetary Commission, created in 1908, he made a thorough study of the leading banking systems in the world. In 1911 this commission urged the adoption of a system of emergency currency based upon the redis-

counting of commercial paper and the creation of a national reserve association with fifteen regional branches. Although Aldrich was not a member of the Senate at the time of the passage of the Federal Reserve Act, his influence on the measure is unmistakable. His plan differed from the one adopted in that it left final control with the bankers rather than with the government.

ALEMBERT, JEAN LEROND D' (1717-83), French mathematician, philosopher and man of letters. He was editor, with Diderot, of the *Encyclopédie* (1751-80), at least for the first seven volumes (1751-57). He wrote for it the *Discours préliminaire* (republished separately, Paris 1894), where he set forth, along with a general classification of human knowledge, a theory of the formation of ideas, and views on the historical progress of the sciences, as well as on the psychological and social factors in their origin and development. A disciple of Locke and of Condillac, his general attitude is empirical, sensationalist and, with regard to metaphysical problems, skeptical.

His classification of knowledge is derived from Bacon, and based upon the distinction between the three essential mental faculties: memory (history), reason (philosophy), imagination (the fine arts). But this order, which with Bacon is purely static, becomes with d'Alembert psychogenetic and even historical: it represents the normal development of the mental processes in an individual man; it epitomizes the real progress of knowledge during the early history of humanity. This order occurs again and again in history, with one important reservation—the period beginning with the Renaissance. The imaginative arts, born of imitation of the ancients, this time preceded the rational sciences. Learning, art and literature, natural philosophy, has been the order of modern progress.

Finally the sciences owe their origin to human needs and their development principally to life in society, for "the ideas which are

acquired by reading and by association with others are the germ of nearly all discoveries." These two ideas of a historical order and of the preponderance of social factors in intellectual evolution were taken up again by A. Comte, who rightly saw in d'Alembert one of the precursors of positivistic sociology.

ALEXANDER I (1777-1825), emperor of Russia. As a youth he was inculcated with liberal ideas by his Swiss tutor Laharpe, and later he had to manoeuvre skilfully between his grandmother Catherine II and his father Pavel I, who were always at loggerheads. This stimulated the development of a temperamental secretiveness, a double personality and a variety of histrionism which remained with Alexander through life. Depressed by the despotism of his father's reign, Alexander hoped in the future to liberalize the government of Russia and to make possible the abolition of serfdom. Immediately upon his enthronement (1801) he created a committee of personal friends to prepare the reforms. The work of the committee yielded little of value because it set itself an impossible task of combining freedom within the law with unlimited absolutism. The machinery of administration was technically improved, rules were promulgated for the liberation of serfs with their lords' consent, but that was all. Defeats suffered in the ensuing wars with France forced Alexander to form an alliance (Tilsit treaty) with Napoleon, which aroused serious opposition in Russia. To allay the unrest Alexander resumed the preparation of reform acts. Speransky drew up a project of a constitutional monarchy, according to which the legislative power was to be shared by the monarch with a representative assembly. Speransky fell from grace through court intrigues by conservatives and his project was not brought to life because of the War of 1812.

The events of this war left a deep impress on Alexander. He became subject to mystic moods, and drafted the plan of the Holy Alliance for the promotion throughout the world of state policies based on the Gospels. During the Vienna Congress and in the following years Alexander was dominated by ideas of legitimism and of restoration of pre-revolutionary regimes

as an antidote to the revolutionary movements in Europe. In domestic affairs he also renounced the liberalism of his earlier years. Alexander completely approved of the regime of unenlightened absolutism, introduced by his closest confidant, Arakcheyev. This led to a recrudescence of revolutionary sentiments among the young officers imbued with western radical ideas, and to the organization of a net of revolutionary secret societies among them. Although the plot became known to Alexander, he was slow to take action. His growing vacillation was also apparent in the foreign policy of the last years of his reign. When the Greeks rebelled against the Turkish authorities, the Holy Alliance headed by Alexander had to support either legitimism against revolution, as it had consistently done heretofore, or Christians against Moslems, in accordance with Russian policy in the Balkans. Alexander hesitated for some time, but was spared the necessity of a decision by his sudden death.

ALEXANDER II (1818-81), emperor of Russia from 1855. The reign of Alexander began during the Crimean War, which brought out the inefficiency of the regime of absolutism and made comprehensive reforms inevitable. Although not in sympathy with constitutional ideas Alexander understood the seriousness of the situation. "Better that reform should come from above than wait until it is imposed from below." The reforms began with the abolition of serfdom (1861); the peasants were granted personal freedom and some land, and the government provided assistance to peasant communities in paying compensation to the former landowners. Other progressive measures included the introduction of local self-government (*zemstvos* and municipalities), of a new court system and of universal military service.

As a whole these reforms removed the most serious obstacles to free economic and social development of Russia, and the country began to progress rapidly along the lines of economy and industrialization. Public opinion expected that the reforms would culminate in the creation of a parliament, but these expectations failed to materialize. A conflict between the government and the liberal groups appeared therefore inevitable and revolutionary activities spread rapidly. The government tried to suppress the movement by police measures which merely made the conflict more acute. Only at the end of his reign did Alexander agree to summon *zemstvo* deputies to some committees of the Imperial Council, but before this measure could be promulgated he was assassinated by the revolutionists.

As regards the non-Russian parts of the empire and especially Finland and Poland, Alexander pursued a conciliatory policy. The Polish extremists, however, drifted toward a radical solution of the Polish problem, so that after the unsuccessful insurrection of 1863 the remnants of Polish autonomy were abolished. Simultaneously a far reaching land reform was carried out in Poland favoring the peasants against the nobility who then constituted the mainstay of Polish nationalism.

Alexander II pursued an aggressive policy in the Middle East (as exemplified by the conquest of Turkestan) and in the Near East. In 1870 Russia reassumed the right, lost after the Crimean War, of maintaining a fleet in the Black Sea. The Russo-Turkish War of 1877-78 resulted in the liberation of Bulgaria and the acquisition of Kars and Batum in Transcaucasia.

ALEXANDER THE GREAT (356-323 B.C.), Hellenic conqueror and statesman. Alexander's inheritance included his ancestral kingdom Macedon, the headship of the Hellenic League founded by his father Philip II, and a mandate to wage a war of revenge, liberation and spoliation against the Persians. The first phase of this war (334-331 B.C.) left him in possession

of all the lands around the Eastern Mediterranean included up to that time in Greek aspirations. Not content with this he succeeded in hurling the Persian king (Darius III) from his imperial throne and in asserting his authority over all the Iranian peoples and the entire basin of the Indus.

On the death of Darius Alexander assumed the kingship of the Persians, and despite Macedonian opposition he drew freely for his administrative and military services on the former Aryan lords of Asia. He carried this policy of fusing the imperial races so far as himself to choose his queen from among the conquered, and to require eighty of his officers to marry Iranian ladies and ten thousand of his soldiers to take native wives. This astounding policy was a recognition of the fact that Macedonians and Greeks alone were too few to dominate the vast alien population involved in the second phase of his war of conquest (331-324 B.C.). It encountered too many national prejudices to have any chance of success after Alexander's premature death (323 B.C.); but through emphasizing the common humanity that underlay differences of race, language, religion and culture it reenforced other cosmopolitan tendencies of the time (the Greek *koiné*, individualistic philosophies and religions, etc.), and entered into the imaginative heritage of Zeno, the founder of the stoic school of philosophy.

The conquests of Alexander prepared the way for larger world unity by breaking down existent states. They permitted the expansion of the Greeks into the East, and this expansion, being one of city-states both because it was the instinct of the Greeks to expand that way and because Alexander conceived city-states as essential for civilizing the fused world of his vision, became a further element of political disintegration. The monarchy of Alexander, although theoretically triune in character—to the Macedonians he was a national king, to the Greek city-states a god-king, to the Asiatics a king by divine grace—was actually one all embracing autocracy. By divorcing government from self-government it facilitated the task for Rome. By uniting Europe and Asia in one denationalized political world the conquests of Alexander favored the rise and spread of the religious ideas which ultimately found expression in Christianity. Such was the compelling quality of the great Macedonian's work and personality that the Alexander of legend

achieved triumphs undreamed of by the Alexander of history.

W., in *Cambridge Ancient History*, vols. i-vii (Cambridge, Eng. 1923-) vol. vi (1927) p. 352-504; Magoun, F. P., *The Gestes of King Alexander of Macedon* (Cambridge, Mass. 1929).

ALFIERI, VITTORIO, CONTE (1749-1803), Italian tragic poet, dramatist and political writer. He was born in Piedmont of an old and illustrious family. In his famous autobiography (*Vita . . . scritta da esso*, tr. by C. E. Lester, 2nd ed. New York 1845; in *Opere*, vol. i) he tells of the superficial education he received at the Academy of Turin, of his lack of interest in study during his youth, and his astonishing indifference to the Italian language and traditions. He spent about six years in the principal countries of Europe, and it was in this period that he first read Dante, Petrarch, Boccaccio, Machiavelli and Tasso. It was not until his twenty-sixth year, disgusted with a life of self-indulgence, ashamed of his ignorance and fired with ambition, that he determined to become an author. At first he wrote in French, but he soon made up his mind to "unfrenchify" himself, and he went to Florence to begin the serious study of the Italian language and literature. Within fourteen years, from 1775—the date of his literary "conversion"—to 1789, he published nineteen tragedies and wrote much verse as well as some noteworthy prose works on political subjects. Between 1786 and 1792 he spent most of his time in Paris and had an opportunity to observe the development of the French Revolution. At first he was favorably disposed toward it, praising in an ode the storming of the Bastille, *Parigi sbastigliato* (in his *Opere*, vol. iii, p. 132-39), but he later regarded the excesses of the revolution as a corruption of true liberal principles. He fled from Paris in 1792 and gave expression to his hatred of the French people and of the revolution in his *Misogallo* (The Anti-Gallican—*Opere*, vol. iv).

Alfieri denounced all forms of arbitrary power and emphasized the necessity of liberty, of government animated by ideals of freedom and regulated by law (consult his tragedies and some of his principal prose works—*Della tirannide*, *Del principe e delle lettere*, *Panegirico di Plinio a Traiano*—in *Opere*, vol. x). His *Bruto primo* (in *Opere*, vol. vi, p. 299-340) is dedicated

to "General Washington, the liberator of America." He wrote a long ode, *L'America libera* (in *Opere*, vol. iii, p. 36-53), exalting the American revolutionary movement. In a chapter of his *Del principe e delle lettere* (in *Opere*, vol. x) entitled "Esortazione a liberar l'Italia dai barbari," Alfieri emphasized among other things the use of literature as a means of achieving Italian unity and sensed the extinction of the temporal power of the popes. His *Bruto secondo* (in *Opere*, vol. vi, p. 385-428) is dedicated to the "future Italian People." In his *Misogallo* he envisaged the unity of Italy and spoke of hatred of the French as the fundamental basis of Italy's political existence. This book is important as an expression of a need for the political, intellectual and moral autonomy of Italy. Alfieri may be considered the father of modern Italian patriotic literature and is renowned for his part in arousing the Italian people to a sense of national consciousness.

ALFONSO X (1226-84), king of Castile, royal scholar and lawgiver, succeeded his father Fernando III in 1252. His thirty years' reign was marked by continued strife with the Moors, fruitless efforts to attain the throne of the Holy Roman (German) Empire, and domestic insurrections resulting finally in his overthrow by his own son Sancho. The title of *el sabio* (the learned), which distinguishes him from all other Spanish monarchs, marks his fame as a man of learning according to the notions of his time. He was fond of astrology (e.g. his lengthy dissertation in the *Partidas* on the significance of the number seven); a work (*Libro del Tesoro*) on alchemy, which had long been cultivated in Moslem Spain, is doubtfully attributed to him; he translated Arabic works, wrote poetry and patronized learning. Yet his achievements as a lawgiver, for which posterity honors him, were then so little appreciated that he made no

attempt to give the greatest of them more than academic force.

Fernando III had planned a comprehensive scheme of codification to relieve the confusion and diversity of Spanish law; and almost immediately upon his accession Alfonso took up this project. After causing the preparation of several preliminary works he produced, about 1260, the celebrated compilation known as *Las siete partidas* (The Seven Parts), which was not promulgated until the reign of his great-grandson in the Cortes of Alcalá (1348). He probably took a direct part in its preparation and thus the influence of his learning was here most permanent. The work is preponderantly a reproduction of Justinian law, the first to appear in a western vernacular. It marks the reception of Roman law in Spain (displacing the native *fueros*) and its extension to her vast colonial empire overseas. It provided a basis for practical legal accord throughout the Spanish speaking world, including Spanish America and the Philippines, long after severance of the political tie.

ALIEN. The attitude toward the alien in modern as well as primitive society represents the crossing point of two contradictory lines of behavior, best mirrored, perhaps, in the etymology of the Latin *hostis* and *hospes*. These types of behavior are indicated, on the one hand, by the self-consciousness of an exclusive group which involves distrust, fear and hatred of strangers and, on the other, by the feeling of mankind, conscious or subconscious, which calls for the honoring and protection of visitors or those without help or kindred. Accordingly the position of the alien throughout social and economic history has been two sided, and has varied with the various currents of racial and national migration. Even open societies, like that of the United States, may close their gates more or less; and a society will always make some distinction between what it regards as "desirable" or "undesirable" aliens.

The civilization of classical times seems to have been the first to rationalize the group con-

sciousness of a large aggregate of territorial units into a superior cultural value, thus making the alien a "barbarian." The extension of Greek culture, and later of Roman citizenship, operated to break down this general exclusiveness and, until the beginnings of European nationalities at the close of the Middle Ages, the natural unit of cohesion against aliens was local, as in primitive times. This consisted either of the tribe (which in most cases meant equally the religious community) or of local settlements deriving from agricultural communities, either intensified into town life or extended into territorial government.

The concept of the alien varies in content and extent with these changing units. In the village community it designated even the landholder of a neighboring village, and he was permitted to hold local property only with the limited rights of an outsider (*Ausmärker* of German folklaw). In the mediaeval town it extended to foreign traders, who were subjected to a stringent guest law. In fact the creation of territorial government, from the jurisdiction of the Carolingian Empire down to the absolute monarchies of early modern times, shows a ceaseless struggle between the principle of *indigenatus* put forward by territorial estates and aristocracies as a claim to self-government, and the principle of an alien magistrature and bureaucracy used by the central authority to unify and standardize the administration of wider areas, whether national or supranational.

Not only political groupings but also racial contrasts sharpen the outlines of the concept of alien, as can be seen in the great commercial races such as the modern Greeks and Armenians and, even more, the Syrians and Jews. The part played by the Jews in the shaping of modern capitalism is well known. It is, however, to be borne in mind that the Jews represent only a marked instance of a well known and universal process in precapitalist society. The infiltration of aliens as commercial and banking entrepreneurs is exemplified in European history by the domination of the German Hanse and the mediaeval Italian and southern French traders, and also by the colonizing activities of the western nations in Asia, Africa and America.

According to the principle of exclusive settlement there is a tendency toward a segregation of these "guests" in special dwelling places. The Jewish ghetto in mediaeval and early modern towns stands as the most marked example of apparently hostile seclusion. Here

it must be remembered that separate alien settlements do not necessarily imply feelings of group hatred or contempt, but simply constitute a means by which two or more communities may associate without giving up their particular customs and traditions. Thus we find Germanic and Slav settlements living independently side by side all over the region of Germanic colonization in eastern Europe, and the splitting up of the modern oriental town or American city into the quarters of different races, nationalities and religions.

Not only in his economic position is the alien distinctive in his foreign surroundings. He is living in a new and strange environment or, if he is part of an alien group, he shares with the group the sense of a barrier between him and the race or nation which is in the position of host. Usually, therefore, he is characterized by a high degree of mobility and freedom from convention. Sometimes this has a positive value, as in the case of the Calvinist refugees from France, England and the Netherlands, who did so much to spread economic and social individualism in the static society based on the traditional ethics of the mediaeval Catholic church. Sometimes it is merely the plasticity and adaptability of a lower cultural stage, such as that of the Savoyard peddler in Europe, the Indian trader in Africa or the immigrant southerner and easterner in America.

Current interpretations of alien psychology have not taken into sufficient consideration the great change that has slowly taken place in the average type of world migrations. From the age of the prehistoric and protohistoric conquests of agricultural by nomadic tribes down to the nineteenth century, the dispersion of man over a larger territory was preeminently the result of superior physical or mental ability. The end of the nineteenth and beginning of the twentieth centuries are marked, on the other hand, by the overflowing of the weak and unprivileged, not only of capitalist and feudal Europe but also of the middle and far eastern empires. This change implies an alteration of methods in the aliens' struggle for existence. Instead of making their way by capacities for direct economic and political organization and leadership, they undercut the labor market and assume the role of critics of the social order which oppresses them. The mobility and unconventionality of the alien have always tended to make him an "objective" and rational judge of conditions that for him lack the character of the "natural,"

and have even made him attach himself to dissenting parties inside the society of his hosts. These qualities are now developing into at least a potential element of social and political unrest. The role of the revolutionary or Bolshevik alien in modern world politics is familiar. Its importance should not, however, be exaggerated. Socialism and anarchism are to a large extent the result of an internal process, a necessary outgrowth of the unhealthy sides of modern capitalist civilization, just as capitalism itself, although on occasion drawing heavily upon alien forces, Jewish or Protestant or imperialist, is essentially an internal process.

The juridical concept of the alien in international law could not but follow the general lines of these changing relations between higher and lower levels of economic and political organization. The old teaching of the founders of modern international law, strongly emphasizing the right of free access and asylum for the alien, closely corresponded to the interest of civilized governments in attracting valuable cultural and economic elements from abroad. Thus the alien law of nations like England, America and Switzerland was an indispensable component of their general policy of self-preservation and competition in the modern political and economic world. But characteristically the turn of the tide, first indicated by the British Aliens Act of 1905, was most clearly expressed in these same countries. Even if the treatment of enemy aliens and their property in the World War and the peace treaties be considered as a transient phase of international legal history, the present state of the problem, in opposition to the abstract rules of the "law of nature," is based on two positive principles. The first is the balancing of aliens' rights and aliens' duties, discriminating against them in the granting of full citizenship; the second is a reciprocity between nations in the treatment of their respective citizens.

ALIEN AND SEDITION ACTS. The Alien and Sedition laws were passed in 1798 by an overconfident Federalist party. The country was expecting war with France, and the X. Y. Z. incident had raised antforeign hatred to the boiling point. The French government was believed to be spreading propaganda through paid agents, and the Republican press, edited largely by foreigners, was hurling virulent and scurrilous denunciation against the government and its officials. To meet this apparent crisis four laws were passed. The Naturalization Act (1 U. S. Statutes at Large 566) increased the period of residence necessary for naturalization from five to fourteen years. The Enemy Alien Act (1 U. S. Statutes at Large 577) authorized the president in his discretion to arrest, imprison or banish enemy aliens. The Alien Act (1 U. S. Statutes at Large 570) gave the president power to expel from the country any alien whom he regarded as dangerous to public peace or safety, or whom he believed to be plotting against the government. The last two acts were to expire in two years. The Sedition Act (1 U. S. Statutes at Large 596) forbade, first, seditious conspiracies or incitements, and second, the publication of any false, scandalous or malicious writing against the government of the United States, the president or Congress with intent to defame or bring them into disrepute, or to stir up hatred against them or to incite sedition, or to aid any hostile designs of any foreign nation against the United States. The maximum penalty for such publication was two thousand dollars fine and two years imprisonment. One accused under the act was allowed to prove the truth of writings alleged to be seditious; and the jury was made the judge of criminality. The act was to expire by limitation March 3, 1801.

The indignation and alarm of the Republicans was great, and justly so. The first prosecution under the Sedition Act was against a Republican member of Congress running for reelection, and all subsequent victims were Republicans. The cases were tried before unsympathetic Federalist judges and juries. While no aliens were deported, about twenty-five persons were

arrested for seditious libel; at least fifteen of them were indicted and ten convicted. Many years later (1840 and 1850) Congress repaid the fines imposed upon the most conspicuous victims. Jefferson and Madison made the laws the basis of attack in the famous Kentucky and Virginia Resolutions (1799), which declared the acts invalid and asserted the right of the states to nullify unconstitutional acts of Congress. The harsh enforcement of the laws cut deep into the public consciousness, and they were an important factor in the Federalist defeat in 1800 and in the final ruin of the party. Nor was the lesson soon forgotten. The War of 1812 was fought without restrictions upon freedom of expression; and during the Civil War, in spite of the most virulent newspaper attacks upon the government, no sedition law was enacted, although certain executive and military restrictions were sporadically enforced.

The constitutionality of the Sedition Act was sustained in the lower federal courts and by three Supreme Court justices sitting on circuit; but the question never came to the Supreme Court. The Alien Act was alleged to be void because it denied jury trial to deported aliens, and because it gave the president judicial powers. At the present time there can be no doubt as to its validity. The Sedition Act was based on the hypothesis, later declared unsound, that there is a federal common law of seditious libel which the statute clarified and in some respects softened. The Republicans attacked the act as an exercise of a power not delegated to Congress, and as a violation of the freedom of press and speech protected by the First Amendment. The weight of opinion is that as a peace-time measure it was void on this last ground. Certainly it went to the very limits of constitutionality.

The whole episode of the Alien and Sedition Acts burned itself indelibly into the American mind and tradition. It became accepted doctrine that freedom of speech and of the press is beyond the reach of any congressional peace-time regulation, and that it includes the right of full and free political criticism. Nor was the sharp punishment meted out to the party which enacted these unpopular laws likely to be forgotten by responsible party leaders. It was not until the World War that Congress again imposed restrictions upon freedom of utterance and publication. And it was no small part of the bitter cost of the World War that it thus provided the occasion for the weakening in a

measure of the traditions of unrestricted freedom of speech and press which were born out of the popular resentment against the Alien and Sedition laws of 1798.

ALIEN PROPERTY. The treatment of alien property in time of war was greatly affected by the growth of trade from the thirteenth to the eighteenth century. It is generally assumed that confiscation was common until the thirteenth century, but there was comparatively little alien property, except ships, to be found in most countries. The beginning of expansion of international trade found its first reflection in the Magna Carta (1215). Article 41 provides that alien property shall be safe in time of war if reciprocity is granted to English property by the national enemy. From that time many influences served to support immunity for private property, evidenced in the main by treaties. Although enemy property in enemy territory was generally confiscated, the practise of confiscating enemy property in one's own territory had gradually become unusual by the end of the eighteenth century, although numerous writers of the eighteenth and nineteenth centuries, failing adequately to distinguish between alien property in one's own jurisdiction and alien property in enemy territory, continued to speak of the "right" to confiscate long after the exercise of the alleged right had been abandoned.

The rule of immunity for private property, which in 1914 was deemed impregnable, was not the result of any outburst of humanitarian sentiment, but rested upon a sound development in political and legal theory which emphasized the essential distinction between private property and public property, between enemy owned property in one's own jurisdiction and in enemy territory, and between combatants and non-combatants. The natural law philosophers of the eighteenth century were not without their influence, proclaiming the conviction that those surviving the devastating effects of unmitigated war should have something left with which to take up again the thread of life. Modern eco-

nomie relations in their international manifestations, being based upon the mobility of capital, also brought the realization of the mutually destructive effects and futility of confiscation.

In the United States a special tradition in this matter had developed. There had been some sequestration of British debts by several of the colonies in the Revolutionary War, and the Treaty of 1783 undertook to restore the right of suit to the British creditors. The effort was not successful, so that the United States in 1802 paid to Great Britain some \$3,000,000 to make good its inability to carry out the treaty promise of 1783. Meanwhile the Jay Treaty of 1794, declaring in Article 10 against confiscation of debts or funds in any future wars of the signatories, had been concluded with Great Britain. Alexander Hamilton, in his defense of this provision of the treaty contained in his famous Camillus Letters, presented the reasons for this policy as lying in the reliance placed by aliens on the hospitality of the country in which they live. His argument may be said to have laid the foundation for American policy, for some forty treaties of like purport were concluded with other countries. They were designed to afford to aliens, resident and non-resident, an assurance of safety for their property, either by permitting its removal from the country within a limited period of six or nine months or by categorically denying the privilege of sequestration or confiscation. Although judges after the War of 1812 and the Civil War, relying upon text writers, occasionally expressed dicta justifying an alleged rule of confiscation, the fact is that the political departments of the government—Congress and the executive—had not authorized the confiscation of enemy property in any war of the United States until 1917.

The several belligerents in Europe at the time of the outbreak of the World War in 1914 enacted measures sequestering enemy property and prohibiting payments to the enemy. There was at that time no idea of confiscation, but the authorization of liquidation made restoration in kind difficult, if not impossible. As late as 1918 the English House of Lords reiterated the time honored doctrine that the property of enemy subjects was not to be confiscated.

The United States adopted a sequestration statute on October 6, 1917. The property of non-resident Germans was to be demanded and held by an alien property custodian as a 'common law trustee' to manage the property and "if and when necessary" to sell it in order "to

prevent waste and protect such property" and to prevent its hostile use against the United States. The first alien property custodian announced that "there is no thought of a confiscation or dissipation of property thus held in trust." As the war proceeded new ideas seemed to develop in the mind of the custodian. He persuaded Congress to authorize what he called "Americanization" of the property and obtained authority under the Act of March 28, 1918, to sell the property as though he were an "absolute owner." Much property was sold at sacrifice prices, although Congress did not intend to authorize confiscation. Most of the sales were made after the Armistice, when no belligerent purpose could have been served. Perhaps the most notorious of the cases was the Chemical Foundation transaction, in which 4500 chemical patents worth many millions were transferred *en bloc* at a uniform price of fifty dollars each to the so-called Chemical Foundation, organized by a group of industrialists and the then alien property custodian. The Supreme Court sustained this transaction as valid under the statute. Seizures were discontinued only on July 2, 1921.

The Peace Conference met in 1919. To the surprise of many thoughtful students there issued from the conference, in the form of Article 297 of the Treaty of Versailles, a provision to the effect that the Allied Powers reserved "the right to retain and liquidate all the property, rights, and interests belonging . . . to German nationals" in the territories under allied control. A similar provision is to be found in the other peace treaties. The proceeds were to be devoted to the payment of certain claims against Germany or German nationals. These claims were in the nature of private debts, claims due to exceptional war measures such as sequestrations, and so-called neutrality claims, which arose before the various countries entered the war. Any balance could be turned back to the owners or to the Reparation Commission for general distribution. The provision was not mandatory on the different allies, each country being left free to liquidate or return the sequestered property. The German government was to indemnify the expropriated private owners.

Most of the European countries—notably England, France and its colonies, Italy and, with minor exceptions, Belgium and Rumania (old territory)—have confiscated the sequestered property. As a matter of grace England

has consented to return amounts up to £1000 to certain persons domiciled in Great Britain and in certain necessitous cases. Not many have been able to take advantage of this concession, it is understood. South Africa has released the property of domiciled Germans and given South African bonds to non-resident Germans for their liquidated property. Italy has released up to 50,000 lire to each enemy owner, but has taken the balance. Japan has released up to 10,000 yen and portions of the balance varying from 20 to 50 percent, retaining an amount sufficient to pay private debts. Most of the South American states have released the sequestered property in full. Canada has not yet determined its final policy, but unofficially appears to be committed to return at least the excess beyond that required to pay private debts. This at least has been the arrangement with respect to Austrian nationals. The British colonies adopted varied practises. The succession states—Poland, Rumania, Yugoslavia, Czechoslovakia—were restricted in their privilege of confiscation, but liquidated the property to some extent and were supposed to pay the proceeds to the expropriated owners. Some differences were made between territory previously possessed, in the case of an existing state, and that newly acquired. Turkey, after its victory over the Greeks at Smyrna, was able to nullify (by Article 65 of the Treaty of Lausanne) that provision of the Treaty of Sèvres which provided for the confiscation of Turkish private property. "Personal effects" were released only in some of the minor countries like Siam and the German colonies taken over by England, but patents and trade marks, unless sold with liquidated businesses, were in all countries returned to their owners. The so-called Young Plan of 1929 recommends that all further seizures or liquidations of German private property in allied countries shall cease. Probably not much property would be affected by this belated renunciation.

The German government has made but a small fractional payment to its expropriated owners, claiming inability to pay more. Germany brought a proceeding before the Dawes Plan Arbitration Commission claiming the right to deduct from the payment to the Allies the amount due to German expropriated owners, on the ground that this was an obligation imposed by the Treaty of Versailles, and that the plan stipulated that all German obligations under the treaty were embraced within its terms. Germany lost the case.

When peace was made between the United States and Germany, it was provided that German private property was to be retained until Germany made "suitable provision" for the satisfaction of American private claims against Germany. These included not merely the claims arising out of private debts, exceptional war measures and neutrality claims, as in the case of the European countries—an amount which would have been limited to about \$50,000,000—but claims of every character. A Mixed Claims Commission was set up in August, 1922, to determine the amount of the claims, with an American citizen as umpire. The awards on private claims, including approximately ten years' interest at 5 percent, are estimated at about \$200,000,000.

On June 5, 1920, a partial release was effected of the property of Germans, Austrians and Hungarians who became citizens of succession states by the treaties of peace, of certain classes of American citizens who by reason of their residence in Germany or other enemy territory had their property sequestered, and of American born wives of ex-enemy citizens. On March 4, 1923, the Winslow Act was passed returning trusts up to \$10,000, and \$10,000 on the larger trusts, together with all income earned after March 4, 1923, up to \$10,000 a year. On March 10, 1928, the Settlement of War Claims Act was passed, which returned 80 percent of the property of Germans and all the income earned since March 4, 1923. The owners of the withheld 20 percent are to receive 5 percent interest bearing participating certificates drawn against the fund to come to the United States under the Dawes Plan (2½ percent of the reparations, after numerous prior charges). For the income on cash in the treasury accumulated between 1917 and 1923, the so-called Unallocated Interest Fund, the owners are to receive non-interest bearing participating certificates. The undelivered sum (about \$75,000,000), together with the early payments to come to the United States from German reparations, is to be paid over to the American claimants against Germany. The property of Austrians has been returned in full, inasmuch as Austria has deposited a sum sufficient to take care of the American claims against that country, probably not over \$4,000,000. The Hungarians will probably receive their property under similar conditions. Two percent is deducted by the alien property custodian from all the trusts, in order that the United States may be repaid for the cost of ad-

ministering the property. The owners are thus paying the United States a substantial sum, in addition to taxes, as a condition of obtaining some 80 percent of their property. Because of the conditions attached to the retention of 20 percent, it seems unlikely that the United States will ultimately confiscate the 20 percent, even if German reparations should break down.

What of the future? The International Law Association at its 1924 meeting in Stockholm adopted the following resolution: "Resolved that this Conference is firmly of opinion that the revived practice of warring states by which they confiscate the available private property of alien citizens is a relic of barbarism worthy of the most severe condemnation." With few exceptions writers throughout the world have condemned the Allied practise of confiscation. It is a reversion to an ancient institution which had been deemed obsolete. Its destructive effects are likely to be considerable. Foreign investments become insecure, and the realization that the safety of foreign private property in war depends not on law but on the preponderance of force, is likely materially to hamper the reduction of armaments. It remains to be seen whether the confiscating countries will compensate the expropriated owners before the policy becomes irretrievable, and whether any legal code, in an effort to prevent the establishment of confiscation as a principle, will reaffirm the traditional rule of the immunity of private property in time of war.

ALIENATION OF PROPERTY may be voluntary, resulting from the intended acts of the owner, or involuntary, through the acts of organized society in forcibly taking the property for the benefit of creditors or of one long in adverse possession, or for the public use. It may be effected by acts *inter vivos*, or it may be testamentary, effective at the death of the owner.

From the Middle Ages down to our own times the power of alienation has been regarded as a necessary and natural element of property. In the language of the Supreme Court of the United States, it is "an inherent attribute of the property itself," but historically it is by no means that. In primitive social orders alienation is quite unnatural. The earliest known form of property was the community ownership of chattels, such as weapons, cattle and slaves, by the family, tribe or village. The community property was for community use, not for sale. Even when growing trade between tribes provided an economic urge for the transfer of chattels, alienation was possible only with the consent of the whole community, evidenced by elaborate ceremonial. Later forms of such ceremonials in proof of transfer are strikingly illustrated by the *mancipium* of the earlier Roman law, the dramatic livery of seisin of land and even of chattels in the Middle Ages throughout Europe, and by divers skeleton survivals in our own time, such as the sealing of written documents, acknowledgment before a notary and registration.

With the increase of trade and the improvement and expansion of political organization, community property in chattels and later in land slowly broke down and disintegrated into individual ownership, with broadening powers of alienation and decreasing requirements of time-consuming attesting ceremonial. Community ownership persisted in the *patria potestas* of the highly developed Roman law, with all its consequent restriction upon the power of alienation. Survivals of it were found in the feudal system of land tenure which during the Middle Ages spread over nearly all of Europe. Even in our own time we have remnants of the primitive institution of community property in the several forms of cotenancy still existing, and particularly in the common interests of husband and wife, such as tenancy by entireties, homestead and other rights of succession, and the "community property" generally recognized in legal systems derived from the civil law, and even in a few of

the American states. Safeguarding the family, even at the expense of business interests, the law will not permit either spouse by alienation to prejudice the rights of the other.

The older complex classification of property, based on the mode and extent of alienation allowed, such as, in the Roman law, *res Mancipi*, alienable only by burdensome ceremonial, and the *res nec Mancipi*, alienable by mere delivery, ultimately gave place, in the law of Rome and of those countries in Europe later deriving their law from Justinian's code, to a simpler and more natural division into movables and immovables, both quite freely alienable by the individual owner, *inter vivos* and by will. But this result was not achieved so easily or directly in England. Before the conquest Anglo-Saxon law made a sharp distinction between movables and immovables. The former were freely alienable, but quite a different rule obtained in regard to immovables. Folkland, which included by far the greater part of the valuable land of the island, held in community ownership, was wholly inalienable, although book-land, consisting of royal grants to religious houses and great men, appears to have been freely alienable. The Norman conquerors brought to England much of Norman law. The simple and natural division of property into movables and immovables was abandoned for the highly artificial and complex classification into personalty and realty. Rights in personalty, left largely to the church courts, in which the influence of the civil law was predominant, remained freely alienable. But the king's courts, in the interest of feudal control, assumed exclusive jurisdiction over the land, which was quickly put in feudal shackles that have scarcely yet been fully cast off. A unique system of feudal tenure was established, in which all land was held of the crown, while the tenant took an interest so narrowly limited that it could be aliened only with the consent of his overlord on the one hand, and of his heir presumptive on the other.

Those holding the land as tenants in chivalry under this system formed a privileged land-owning class who had no interest in trade, and dimly perceived that so long as they controlled the land of England they could control the people who must live on the land. Naturally they resisted every effort to facilitate its alienation, but such a static condition of property could not long survive. With trade increasing and lack-land burghers growing richer, with

population expanding and more and more mouths calling for corn, the restraints on alienation began to give way. The judges, almost uniformly sympathetic with the demand for freer alienation, first cut off the interest of the heir presumptive, and later defeated the lords' expected reversion by holding that feoffment to A and the heirs of his body created a fee conditional upon the birth of issue to A. The lords countered with the enactment by Parliament of the statute *De Donis* (1285), which created estates tail. But five years later in the statute *Quia Emptores*, known as the "charter of free alienation," they were forced to assent to the validity of feoffment in fee simple without the consent of the overlord, securing thereby the abolition of subinfeudation, which had hitherto greatly reduced the value of their feudal services.

The inalienable entails set up under the statute *De Donis* did not long remain unchallenged. Fines, or collusive suits, were used to bar entails but could not defeat the vested interests of reversioners and remaindermen. It was not until 1473, nearly two centuries after the creation of entails, that landed property was freed from this "perpetuity" by the decision in *Taltarum's* case. This bold piece of judicial legislation enabled the tenant in tail in possession, by the fictitious proceedings of a collusive suit termed "suffering a common recovery," to bar the entail and create in the plaintiff an estate in fee simple absolute. In the meantime the development of "uses" in land had greatly facilitated alienation. In 1535 the Statute of Uses much simplified the formalities required for the conveyance of land, while in 1541 land was made alienable by will.

By this time the evils consequent upon unreasonable restraints on alienation were fully recognized by the courts, but a new form of "perpetuity" soon appeared by reason of a decision in 1620 that certain future interests, known as executory devises and uses, did not share the destructible quality of contingent remainders. This ruling, threatening to take land out of trade channels altogether, was met by another famous achievement of judicial legislation known as the rule against perpetuities. This rule, in its fully developed form, may be stated thus: any estate so limited that it may, under any possible circumstances, vest in right at a later date than twenty-one years after lives in being at the time of its creation, is absolutely

void. In form it imposed a restriction upon the power of alienation. In fact it kept property open for the uses of business by freeing it from a tangled web of remote future interests. In like manner the long series of mortmain acts, beginning with *magna carta*, by prohibiting the transfer of lands to religious houses, thereby kept it from the "dead hand" of the church and made it available for the needs of commerce.

The rule against perpetuities being judge-made and not arbitrarily fixed by the words of a statute, its operation is highly elastic. Its application goes no further than the mischief sought to be remedied. Thus it does not affect an interest, however remote, if it is so limited as to be always in the control of the tenant in possession. For that reason it has not been applied to covenants to renew long term leases, or to rights of reverter and rights of entry, because such interests are not believed in fact to clog alienation.

The next move of the landowning class, in their struggle to retain control of the land by restricting alienation as far as possible, was the invention of the "strict settlement," a method of marriage settlement by a series of entails which, although not legally a perpetuity, nevertheless, under the influence of family and class pressure, in fact rendered a considerable part of the land of England inalienable in the hands of the landed gentry. This situation was met by the Settled Land Act of 1882, confirmed and extended by the Law of Property Act of 1925, under which the freehold tenant in possession has the unrestricted power of alienating in fee simple. This legislation also abolished primogeniture.

The American colonists brought with them to the New World the fully developed idea of the common law that unreasonable restraints upon alienation of property and perpetuities are contrary to public policy and void, but in determining just what restraints are unreasonable there appear some curious and interesting variations from the law of England. The most notable of these is found in the curious doctrine of spendthrift trusts. In England it is settled policy that any beneficial property right available to a person *sui juris*, whether by way of trust or otherwise, is also available to his creditors; but it is now equally well settled in all but a very few of the American states that, by the use of apt words in a deed of trust, an interest for life, at least, may be given in any

form of property, real or personal, which is beyond the power of the spendthrift to alien, or of his creditors to seize. The English rule results from an appreciation by a nation of traders that honesty is not merely the best policy but the only policy to safeguard commerce. The American doctrine seems to result from a reverence for the wishes of a grantor or testator which outweighs the interest of trade and extends to the spendthrift the protection always allowed to married women, to whose separate use trust property may be devoted freed from the perils of unwise alienation, voluntary or otherwise.

ALIENIST. The word alienist has largely been used in the past as synonymous with the word psychiatrist, but in recent years there has tended to grow up a distinction between the two terms. While psychiatry is used to cover the whole specialty of medicine which devotes itself to the care and treatment of mental disease, the practise of the alienist, or alienistics as it is sometimes referred to, has to do only with the determination of insanity in the legal sense, insanity being conceived to be only certain aspects or degrees of mental illness limited in accordance with legal definitions. Mental disease is therefore a medical or scientific term, while insanity is the legal and sociological term.

The function of the alienist, which is essentially that of the expert witness, is in theory to give the results of his scientific experience with mental disease in general, and in particular with reference to the case in hand, for the assistance of the court and the instruction of the jury. As an expert he is not confined to testimony as to facts. His testimony is essentially opinion evidence, and on the witness stand he is called upon to give his opinion of the bearing of certain symptoms upon certain legal issues involved, such as responsibility in criminal

actions and testamentary capacity in civil ones.

The testimony of alienists has in recent years fallen somewhat into disrepute because they have been pitted against one another in equal numbers; and because of the technical character of their evidence and the fact that they contradict each other, juries have tended to disregard it. Many efforts have been made to correct this state of affairs. The most outstanding suggestion is to employ state alienists who occupy a neutral position in the cause at issue and who may therefore be cross-examined by both the defense and the prosecution. Such a course does not limit either the defense or the prosecution from employing additional alienists, but it is felt that the neutral position of the state alienists would materially increase the weight of their testimony. In practise, however, the problem of the expert testimony of alienists remains in a very unsatisfactory state.

The psychiatrists, however, are coming into court work from a somewhat different angle and are rendering most valuable service. They are rarely seen on the witness stand, but usually make scientific investigations into the mental condition of individuals who come before the courts and render their reports directly to the court for its guidance. They have been of especial service in the juvenile courts, but are coming now gradually to do similar work in the criminal courts.

The taking over of this pre-trial work by the psychiatrist has made less and less necessary the employment of the alienist as an expert at the trial, and it is perhaps in this direction that one may look for the solution of the expert witness problem, so far as it relates to the question of mental disease and insanity.

ALIMONY, as the term is popularly understood, denotes the obligation of a husband to continue to support his wife and any dependent children after absolute divorce or

judicial separation. As such it is generally understood simply as a provision for maintenance.

Historically, however, alimony is to be conceived as any compensation to either spouse for the disruption of the marriage. In the broadest sense it is an adjustment of the economic relations of the spouses. In its origin and evolution it is as much a penalty to prevent divorce as a provision in case of divorce. In ancient patriarchal societies, where divorce was absolutely unlimited for the husband, he might put his wife away without providing for her at all. In a more advanced stage a fixed penalty is often assessed against the husband if the wife is innocent of offense. This right probably arose to prevent blood feuds with the wife's relatives. Thus under the Code of Hammurabi a husband who divorced his wife without cause had to forfeit to her one mina of silver, and in addition restore her portion.

This latter provision marked an advance representing a greater stability of matrimonial and economic institutions. Alimony is now imposed as a positive legal duty which can be controlled by the spouses only to a very limited extent, but in its origin it was largely contractual. The husband's unlimited right of divorce began to be controlled by marriage contracts among the ancient Egyptians, Greeks and Jews. Indeed the Greeks finally went so far as to declare a marriage without a property settlement for the wife to be invalid and void.

The Roman law, which has had most influence upon western institutions, exhibited all these stages of development. Under the *manus* system of marriage the wife had no rights at all, but by the time of Justinian, when husband and wife were upon an equality before the law, it was established that a guilty wife lost her *dos*, and a guilty husband his *donatio propter nuptias*. Both spouses were liable to contribute to the support of the children. In the absence of marriage settlements, however, the guilty spouse forfeited one hundred pounds in gold. In case of divorce by mutual consent the parties could make any arrangement they wished about their property.

Perpetual alimony for the wife followed as a necessary metaphysical and economic corollary of the mediaeval church's doctrine of the indissolubility of marriage. The Protestant reformers who could allow divorce only by conceiving one of the spouses as a criminal emphasized particularly the penal character of alimony. Much

of the extravagance of the present Anglo-American law of alimony is to be attributed to the persisting influence of Reformation ideas which passed from the English ecclesiastical courts into the common law.

The present rules of alimony exhibit many of these survivals. Judges on the whole are still inclined to look upon alimony as a punishment. Its amount is usually affected by the degree of the husband's guilt, and is proportioned not so much to the wife's necessities as to her husband's financial capacity. It may be as high as one third of his income. Although the wife has to be innocent, she remains entitled to alimony if only guilty of lesser matrimonial offences than adultery. A wife may get temporary alimony (*pendente lite*) pending the very determination of her right to divorce. Alimony does not automatically cease upon her remarriage. Imprisonment for debt has long ceased to be popular, but a divorced husband may be incarcerated for failure to pay alimony. The alimony laws thus make marriage an opportunity for the determined "gold-digger." It is to be doubted, however, that alimony is related to the recent increase of divorce. If the wife is encouraged, the husband is correspondingly restrained.

The first step to reform the alimony laws will be taken when the principle is recognized that the mere fact of marriage can only metaphysically be regarded as a proper basis for alimony. This view would permit the duration of the marriage to be taken into account. The present economic emancipation of women should dictate the substitution of an equitable liquidation of the economic claims of the spouses upon each other for alimony. Even in the absence of a legalized institution of community property the intimacy of marriage creates its natural equivalent. The woman who has made her household her career would certainly be entitled to some allowance when the value of her services to her husband are considered. In any event the sexual disabilities of women remain, and the wife with dependent children should be entitled to adequate protection. In three American jurisdictions, Massachusetts, North Dakota and Ohio, statutes now give a husband the right to alimony under certain circumstances when he is the injured spouse. This reciprocity may be just in the present impasse but it represents a dubious reform. Where the conduct of one of the spouses has been such as to injure the other in health, reputation or property, a mutual right to damages might be allowed in the liquidation.

Many of these reforms have long been law in various European countries. The influence there of the Code Napoléon restored much of the enlightenment in matrimonial relations which characterized Roman law. The freedom with which alimony is granted in American states is in part a reflex of our economic efflorescence and social undifferentiation. But the general equivalent of the community and dotal property systems on the continent have restrained alimony. When granted it is limited mostly to cases of actual need. The husband, it is true, often has a right to alimony when incapacitated. The wife generally may be liable for a contribution for the support of the children. There was no right to alimony at all in Sweden until the new law of 1920 which established it only in cases of actual want. The reciprocal claims for specific injuries are also law now in the Scandinavian countries, but have been long allowed in Switzerland. In most countries where both parties are at fault in any way neither is entitled to alimony. Finally it should be noted that the right to divorce by mutual consent in Russia, Austria, Belgium, Rumania and the Scandinavian countries is itself a solution of the alimony problem, for then the parties may come to an amicable understanding upon the subject without the intervention of the law.

ALISON, ARCHIBALD, BART. (1792-1867), historian. He was born at Kenley, Shropshire, of Scottish parentage, studied at Edinburgh University, joined the Scottish bar and in 1834 became Sheriff of Lanarkshire. Before this he had entered literature as a contributor to *Blackwood's*, in whose pages he advocated the undiluted Toryism of the day, and he had long been collecting material for a *History of Europe from the Commencement of the French Revolution in 1789 to the Restoration of the Bourbons in 1815*.

This work appeared in ten volumes at Edinburgh between 1833 and 1842, and had a prodigious sale; by 1848 America alone had bought 100,000 copies. Assuming the role of political philosopher, he made the mistake of writing as a violent partisan. He frankly admitted that he wrote to illustrate certain theories. One was the comfortable notion that to disturb the established oligarchic order of society was to challenge destiny. With Alison in mind Disraeli, in *Coningsby* (1844), made Mr. Rigby speak of "Mr. Wordy's History of the late war" as "a capital work which proves that Providence was on the side of the Tories." Critics of the liberal persuasion had no difficulty in making matchwood of his most confident dogmatism. Later he brought the narrative down to 1852 in his *History of Europe from the Fall of Napoleon in 1815 to the Accession of Louis Napoleon in 1852* (9 vols. Edinburgh 1852-59), which gave him the opportunity of attacking the 1832 Reform Act, the 1844 act restricting the paper currency, and the abolition of the Corn Laws. Whenever he touched either economics or politics in the *History* or in his other writings it was as a die-hard Tory. He naturally sided with the South in the American Civil War.

W. H. DAWSON

ALLAN, HUGH, BART. (1810-82), Canadian captain of industry. He was born in Saltcoats, Ayrshire, Scotland, and received a thorough apprenticeship in Glasgow and Montreal in the management and business side of shipping and shipbuilding. His contributions to Canadian economic development consisted primarily in his ability to meet the demands of shipping in capital, organization and technique during the difficult period of technological change from wooden sailing vessels to iron steamships. The eventual success of the shipping industry was accompanied by the tying-in of that business with various other lines of development, industrial, mining and financial (Merchants Bank), a process in which he played an important part. The Pacific Scandal, however, is evidence that the railroads, with their heavier demands for capital and organization, were largely beyond his control.

Consult: Dent, J. C., *The Canadian Portrait Gallery*, 4 vols. (Toronto 1880-81) vol. ii, p. 38-40; Innis, H. A., *A History of the Canadian Pacific Railway* (London 1923) p. 75-83; Bowen, F. C., *History of the Canadian Pacific Line* (London 1928) p. 3-45.

ALLAN, WILLIAM (1813-74), English trade union leader. He worked as journeyman engineer until his appointment (1847) as general secretary of an engineering workers' union. Allan favored amalgamation of the various engineers' unions and contributed largely to the formation of the Amalgamated Society of Engineers (1851), of which he was general secretary for over twenty years. During this time the numerical and financial strength of this national society of skilled craftsmen became so impressive that many unions took its constitution as a model. It provided substantial unemployment, sickness and other friendly benefits; and the moderation of its policy contrasted with the aggressiveness and violence of various old-fashioned local unions. William Allan instituted an elaborate system of financial control, but the amount of administrative routine involved, together with his extreme caution and desire to conserve the society's funds, resulted in lack of constructive trade policy.

William Allan was associated with Robert Applegarth in the informal "cabinet" of trade-union leaders who guided the movement resulting in legislation for full legal status of the unions (1871). The success of this movement was facilitated by the favorable impression on public opinion created by the moderation and financial integrity with which Allan's society, and others modeled on it, were administered.

J. H. RICHARDSON

ALLEGIANCE is a concept which, despite its narrow legal meaning, is also of significance to political philosophy, for it connotes the emotional ties which bind the individual to a political group or association and to the symbols which represent it. The word allegiance is commonly related to the Latin *ligius* (French *lige*) and its derivatives *ligeantia*, *ligeitas*, etc. These terms denote feudal relationship; the adjective *ligius* therefore also occurs in connection with *homagium* when it characterizes unconditional homage. The English kings seem to have succeeded at an early period, certainly in the twelfth century, in establishing their exclusive right to unconditional feudal superiority, so that wherever *ligium homagium* is done, the express reservation of faith toward the king is required (for an interesting case cf. Coke, *Institutes*, pt. i, sect. 85). It seems that this claim of the king was effectively linked with another and more ancient institution going back to Anglo-Saxon times, namely with the

oath to keep the king's peace, i.e. not to commit certain crimes nor to conceal the knowledge thereof. This oath was originally required of every man (cf. Laws of Eadmund I and Laws of Canute c. 21, quoted in Stubbs, *Select Charters*, 9th ed. Oxford 1913, p. 77, 87), but it appears to have been gradually restricted to those who did not do homage to the king, such as magnates, knights and their relatives, clerks, *liberi homines* and the like (Bracton, *De legibus Angliae*, vol. ii, f 124b). Whether or not this oath might be associated with the origin of frankpledge (cf. W. A. Morris, *The Frankpledge System*, New York 1910, ch. i, and the literature cited there), it is likely that it became associated with the view of frankpledge under Henry II. It has been suggested by Maitland that frankpledge and the tithing to which it belongs served as a foundation for a part of the system of administering justice initiated by Henry I and developed by Henry II (Assize of Clarendon c. 1. in Stubbs, *op. cit.*, p. 170); for "under the influence of the assize of Clarendon the duty of producing one's fellow-pledges to answer accusations seems to have been enlarged into a duty of reporting their offences, of making presentments of all that went wrong in the tithing" (Pollock and Maitland, *History of English Law*, Cambridge, Eng. 1895, vol. i, p. 557). This suggests that the oath of allegiance or alleageance, as it was often called until the seventeenth century, is the result of merging two oaths, namely the oath administered in connection with the allegiance of offenses violating the king's peace and the oath of fealty administered in the confirmation of the liege homage, later called the natural ligeance due to the king. If this hypothesis were accepted, it would solve the etymological problem involved in deriving the word allegiance from *ligius*, because it would explain the prefix "al-" and also why this peculiar concept should have arisen in England alone.

For certainly on the continent of Europe kings were not successful in advancing similar claims, and it was only in the fifteenth century that the French kings definitely established this right. In Germany, on the other hand, the *ligium homagium* as well as the feudal tenancy to which it belonged gradually disappeared after the efforts of the Hohenstaufen emperors, particularly Frederick I, to secure *ligium homagium* for themselves had been balked. The general development of feudal institutions in central Europe was unfavorable to such a doctrine; for the principle *nulla terre sans seigneur*,

which came to prevail in England even more widely than in France, never gained ascendancy in many parts of central Europe. As a result the concept of allegiance is peculiar to English law and has no real equivalent in French, German, Italian and other continental jurisdictions.

In England the concept of allegiance was effectively linked with the crime of treason by the statute 25 Edw. III c. 2., which defines the offenses which may be held to be treason. The gradual expansion of royal pretensions is evidenced in the reign of King Richard II by the statute 21 Rich. II c. 3., which made high treason merely the purpose and intent of killing or deposing the king, without any overt act to demonstrate it. Although these particular enactments were repealed under Richard's successor, the same tendency exhibited itself again under Henry IV and Henry VIII (Coke, *Institutes*, pt. iii, and Blackstone's *Commentaries*, bk. v, ch. vi) and Elizabeth. Particularly under the two latter monarchs there began the tendency to use breach of allegiance, that is, treason, in their struggle with the church, a tendency which culminated in the reign of James I, who might properly be described as the philosopher of allegiance, since three fourths of his writings center around this concept. It was the feudal proprietary nucleus of the concept of allegiance and its ancient relation with a most solemn oath which made it possible for James I to brand a breach of it as heresy. Moreover the notorious Gunpowder Plot strengthened his hand in insisting upon the complete separation of civil and ecclesiastical allegiance, at which his legislation of the next few years is aimed (3 Jac. I c. 2, 4, 5 and 7 Jac. I c. 2, 6). The center of this legislation was of course the oath of allegiance itself, in which the recognition of the pope as a temporal lord was foresworn. The famous decision in Calvin's case (v. 7 Coke Rep. 1; also to be found in Howell's *State Trials* vol. ii, 1608, no. 85), established this as the authoritative interpretation of the legal concept of allegiance for some time to come.

When in the succeeding century the people politically organized came to inherit the exercise of the power which the kings had consolidated, the concept of allegiance underwent a gradual transformation. While allegiance was formally still due to the king, it was in fact owed to the body politic of which he was the formal representative. This classical common law notion of perpetual allegiance as it prevailed in the

England of the seventeenth and early eighteenth centuries is in many respects the most powerful expression of the national state in its rigid seclusion and insular self-sufficiency. As far as the individual was concerned, he was considered to owe this allegiance from the moment of his birth on English soil. He could not renounce it except by permission from the king in Parliament. It was the basis of all his rights and duties as an Englishman. Its feudal origin is clearly evidenced in the fact that only such allegiance gave a man the right to hold real property in England. Although an alien might acquire the status of subject through an act of Parliament, the procedure for effecting this was attended by cumbersome formalities.

Such a rigid concept was bound to be subjected to numerous alterations as modern trade began to develop, and the classical doctrine of allegiance as enunciated in Calvin's case (1608) was slowly weakened by many minor exceptions. This process eventually led to the Naturalization Act of 1870 (33 Vict. c. 14) which adapted the status of subjects to modern conditions, accepted the principle of free interchange of citizenship and thereby deprived the concept of allegiance of most of its significance.

This development had been anticipated by the fate of the concept of allegiance in the United States. In the early years of the republic the prevailing opinion seemed to be that a citizen could not divest himself of his allegiance except under the sanction of the law of the United States, and that until some legislative regulations were made, the rule of the common law that allegiance is perpetual must prevail (Talbot v. Janson, 1795, 3 Dal. 133-70). On the other hand, Caleb Cushing expressed the opinion, when he was attorney general, that the "doctrine of absolute and perpetual allegiance is inadmissible in the United States. It was a matter involved in, and settled by us by, the Revolution, which founded the American Union" (p. 166 in 8 Op. Atty. Genls. 139-69). In expounding the same doctrine Mr. Justice Story said that allegiance is "nothing more than the tie or duty of obedience of a subject to the sovereign under whose protection he is" (Ingles v. Sailor's Snug Harbor, 1830, 3 Peters 99-191). The complication introduced by the famous Dred Scott case (Dred Scott v. Sandford, 1856, 19 Howard 393-633) was swept aside by the Fourteenth Amendment, which significantly does not speak of allegiance at all but of an oath to the Constitution of the United States.

The same tendency later manifested itself in congressional legislation dealing with citizenship, expatriation and the like (Act of July 27, 1868). The citizen either expressly or impliedly takes an oath to support the constitution and the laws of the United States, and no personal relation is entered into with the government, legally speaking. It is a relation among the citizens that is involved and a pledge of obedience to the laws, which the citizens make for themselves (*United States v. Wong Kim Ark*, 1897, 169 U. S. 649-732). Still, law dictionaries nowadays usually distinguish three kinds of allegiance, natural allegiance, acquired allegiance, and local or temporary allegiance (for the latter see *Carlisle v. the United States*, 1872, 16 Wal. 147-56). Allegiance is there defined as "the obligation to fidelity and obedience which the individual owes to the government under which he lives, or to his sovereign, in return for the protection which he receives." This definition, when applied to the threefold distinction we have just indicated is lacking in definite meaning and prone to lead to confusion. This is most clearly shown by the cases of double allegiance which arise from the doctrine of dual nationality in international law when a naturalized citizen's country of origin refuses to recognize his right of expatriation.

The significant fact is that those relations of political loyalty which were formerly the result of allegiance are now the result of nationality. For the most part the only relations for which the term allegiance is really needed in modern law are those which exist between a resident alien and the state under whose jurisdiction he lives, due perhaps to the fact that in its territorial aspect the modern constitutional state resembles its feudal predecessor. The international mobility of population today has produced migrant nationals who wish to change or retain their original citizenship. This has given a new vitality to allegiance since it may now be used as the instrument whereby governments, before granting citizenship to an alien, assure themselves that he does not adhere to ideals and beliefs which are contrary to the prevailing national mores and which make an oath of allegiance without reservations impossible. The oath of allegiance, which has always been found useful in test acts motivated by a fear of the pope, may also be used even today in periods of subversive movements as a protection against radical organizations; in this connection it may even be applied to native citizens

seeking public employment or entering public office. In another direction the concept of allegiance may take on a new lease of life in the recent tendencies to emphasize the role of the crown in rebuilding the British Empire in terms of a free commonwealth of nations. One might also mention the oath of "allegiance" to be taken by members of the Parliament of the Irish Free State (Art. 4 of the Peace Treaty). But even here it ought to be noted that the allegiance is to the constitution, and that the faithfulness to the king is "in virtue of the common citizenship of Ireland with Great Britain."

While the legal significance of allegiance is not great at present, its broader philosophical implications have entered into the pluralistic attack upon the classical theory of the state and sovereignty. For the emotional ties which bind the individual to his state and his country of birth cannot be separated clearly from the emotional ties which bind that same individual to other groups or communities and the symbols which represent them. The view of allegiance taken by monistic theories of the state varies with the reason advanced for the necessity of a supreme authority. The theory which emphasizes the natural necessity of a unitary authority sanctioning the body of legal rules upon which all other groups depend for their existence treats allegiance as a phenomenon of nature, expressive, as Blackstone says, of a debt of gratitude. To the theorist, however, who emphasizes the purposive cooperation of free-willing citizens sanctioning the legal rules upon which other groups depend, the duties of citizenship express the binding force of the actions implied therein much more adequately than does allegiance.

CARL JOACHIM FRIEDRICH

ALLIANCE. When three or more states exist in proximity they tend to group themselves into opposing political alliances, either for self-defense, or for aggression, or to preserve the status quo. This was the case among the city-states of ancient Greece. With the development of a single great empire, like that of Rome or of Charlemagne, embracing the larger part of the known world, alliances no longer played so important a role. But with the break up of Charlemagne's empire and the formation of many feudal kingdoms, principalities and cities, political alliances again revived and often became highly effective. Popes, anxious to wield sovereign authority and to prevent the rise of any strong rival state in Italy which might endanger their own temporal power, were commonly the focal centers of mediaeval alliances. During the Italian Renaissance alliances were formed and dissolved with kaleidoscopic rapidity, for reasons which Machiavelli has set forth so shrewdly and entertainingly in *The Prince*.

With the growth of modern national states since the sixteenth century, alliances have commonly aimed to prevent any one state from securing the hegemony of Europe. England allied with the Dutch to prevent the domination of Philip II and of Louis XIV; Sweden, France and the German Protestants allied during the 'Thirty Years' War against the power of the Jesuits and the Hapsburgs; Austria, Prussia, England, Russia and lesser states joined together against the contagion of French revolutionary ideas and the domination of Napoleon.

Bismarck may be regarded as the master hand in making alliances in recent times. His victories of 1864, 1866 and 1870 were partly made possible by his skilful diplomatic arrangements. After 1871, fearful of a possible French war of revenge and anxious to preserve undisturbed his newly created German Empire, Bismarck first brought about the "League of the Three Emperors" of Germany, Austria and Russia, which was to defend monarchical solidarity against the rising tide of international socialism, and to maintain the peace and status quo of

Europe against possible moves of France or others to upset it. This league, solidified into a formal very secret alliance in 1881, virtually secured the domination of the three eastern emperors until Bismarck's dismissal in 1890, but was seriously weakened in the years 1878-81 and 1877-90 by the rivalry between Austria and Russia in the Balkans and by the growth of pan-Slavism. In order further to strengthen Germany Bismarck made a defensive alliance with Austria in 1879, by which Austria and Germany agreed to give full armed assistance to each other if either were attacked by Russia, and to observe a benevolent neutrality if either were attacked by a power other than Russia (such as Italy or France). In 1882 Italy was admitted into alliance with Austria and Germany, thus forming the Triple Alliance, and in 1883 Rumania adhered by alliance to this group.

To offset this quadruple combination dominated by Bismarck, Russia and France gradually overcame the mutual antagonism arising from republican radicalism on the Seine and reactionary absolutism on the Neva, and formed the Franco-Russian Alliance. Continental Europe was now divided into two groups so balanced against one another that neither cared to risk the uncertainties of war.

England, meanwhile, began to experience the difficulties of continuing a policy of "splendid isolation." In the years 1898-1904 she negotiated successively for friendly understandings with Russia, Germany, Japan and France. The negotiations with the first two proving abortive, she made an alliance with Japan in 1902, and an understanding (*entente*) with France in 1904. This was extended into the Triple Entente by an understanding with Russia in 1907. Henceforth the Triple Alliance and Triple Entente, standing face to face, caused a dangerous tension in international relations which contributed to the general conflagration in 1914.

Alliances may be of various types, public or secret, offensive or defensive, or with either general or limited objectives. But these various types are not always sharply distinguishable and the distinctions tend in practise to disappear.

This is evident in a few outstanding examples.

The Alliance of the Three Emperors of 1881 is a good example of a secret alliance, and the secret was so well kept that its very existence was not known until revealed by Goriainov in an article in the *Izvestia* (News) of the Russian Ministry of Foreign Affairs (no. 2, 1915) which appeared in English in the *American Historical Review* (vol. xxiii, 1918). On the other hand the Austro-German Alliance of 1879 was also secret but contained a clause that if Russian armaments grew menacing the two allies would inform the czar that they would consider an attack on either of themselves as an attack on both; and in 1887 Bismarck revealed this fact to Russia. The terms of the Franco-Russian Alliance, and most of the clauses of the Triple Alliance, were kept secret; but this secrecy did not prevent the statesmen of Europe from being perfectly aware of the existence of these alliances, or from surmising pretty correctly their substance.

There is a twofold objection to secret alliances. At home the minister who contracts one may deceive his own fellow citizens and impose obligations and dangers on them which public opinion would not have sanctioned; and abroad the fact that an alliance is known to exist whose terms are secret causes dangerous suspicions and fears, because men are more prone to suspect and fear what is vague or uncertain. To avoid this double danger alliances are sometimes made public, as in the case of the Anglo-Japanese Alliance of 1902. The constitutions of some democratic states, like France and the United States, do not permit the executive to make secret treaties of alliance; but in practise this constitutional limitation has sometimes been evaded by an "exchange of notes" or a "military convention," as in the case of the Franco-Russian Alliance of 1894, which has the practical force of an alliance but which, not being drawn up as a formal treaty, technically does not have to be laid before the legislature for ratification.

Alliances commonly include a statement that they are defensive. Both the Triple Alliance and the Franco-Russian Alliance were originally essentially defensive in character and purpose. But the ambitions of Austria and Italy tended to give the Triple Alliance an aggressive character, so that Germany often had to restrain her partners and warn them that the alliance was not an acquisitive organization but an insurance company. Similarly the Franco-

Russian Alliance, originally defensive in essence, tended to become deformed into an offensive combination through Poincaré's support of Russia's policy in the Balkans.

An alliance may have general objectives, in which case the allies agree to support each other in case of war, and not to make a separate peace until the common enemy has been defeated and each victorious ally has achieved satisfaction. Or an alliance may have a limited objective, like that between England and Japan, which related only to the Far East. More often, however, no such distinction is observed. The same treaty of alliance often not only promises general support but also stipulates the limited conditions under which it is to be given, or the special gains which each victorious ally demands for itself.

Alliances have sometimes served as steps toward federation or the formation of international organizations, like the Delian League, the Hanseatic League, the Holy Alliance or the League of Nations. Where such an international organization has been formed, especially if it is wide reaching and aims to preserve peace and the status quo, there is less place for alliances of the ordinary type. Thus, since the establishment of the League of Nations, though alliances and ententes exist, they play a much less important role than they did before 1919, partly because League members are not permitted to make secret alliances (all treaties of members must be registered with the Secretariat of the League), and partly because the League's machinery for preserving peace and the penalties it imposes for war not only lessen the need for special defensive alliances but also render more hazardous the execution of offensive alliances.

ALLOTMENTS. The term allotment has always meant any parcel of land allotted or given to a person on the division of an estate in lands; but it became of special significance in English terminology during the chief period of the enclosure of the English common fields, 1760-1845. After 1790 it began to have a specific meaning best conveyed in the phrase of the time, "an allotment to the labouring poor." In economics the term as used from 1820 to the end of the nineteenth century signified a small plot of land occupied by a working man and cultivated to supplement the income from wages. This distinguishes the British allotment movement from continental efforts to retain rural workers on the land, for in most European countries the intention was that holders of small plots should substitute individual cultivation for employment for wages. In the beginning of this century, however, when the "allotment movement" in English urban areas gathered strength, the use of allotments spread to classes other than manual workers; in these communities the importance of subsidiary income yielded by cultivation was small. Some urban and suburban groups of allotment cultivators consist mainly of skilled artisans and small traders who hold and cultivate for personal interest and for leisure occupation, quite as much as for purposes of material production.

The earliest allotments were provided for the rural poor, recently deprived of their rights or privileges on the commons or wastes of their parishes. In some areas land was so allotted between 1760 and 1790, but the provision of land for this purpose became more general after 1790 when it had gained the support of influential persons like Arthur Young and Sir John Sinclair. An act of Parliament of 1801 (41 Geo. III. c. 109), relating to the conditions of enclosure, contained several clauses which recognized the right of the poor to participate in the division of common lands, particularly as compensation for their privileges of taking fuel from the common wastes. This, however, did not apply to cases in which the poor were specifically excluded by private enclosure acts; the provision of allotments in all cases was made compulsory only by the General Enclosure Act of 1845. Another enactment of 1819 gave to parish officers, churchwardens and overseers of the poor authority to hire land or, with the consent of the lord of the manor and the inhabitants, to enclose waste land and to let it to the

poor. By 1830 the system of supplying plots of land to manual workers or unemployed persons had also spread to towns.

Although the movement at this time was in part an effort to restore the use and control of land to the agricultural and industrial worker, it is more significant as an attempt to provide sources of income to supplement wages insufficient to maintain families. Economists and social reformers were divided in their opinions as to the results of allotments. While all agreed that the sobriety, industry and thrift of the landless workers would be increased thereby, some feared that workers would be enabled to become too independent to work for wages, and others maintained that the opportunity of obtaining subsidiary income would lead to oversupply of labor and to further distress. The Poor Law commissioners in 1834 decided that the practise of letting land as allotments, beneficial to lessor as well as to lessee, and known to be so, might be left to the care of the self-interest of those involved. This led to a cessation of public activity in provision of allotments after 1835. Thus ended the formal connection between allotments and the system of poor relief, but the economic connection was to remain until the end of the nineteenth century.

The prejudice against the larger plots of land for laborers broke down very slowly, but by 1870 a clear distinction had developed between "garden" allotments, plots of one eighth to one fourth of an acre, and the larger "field" allotments, plots of one fourth of an acre to two acres devoted to the growing of cereal and potatoes. From 1880 on the former may be regarded as a natural amenity of country life for those people whose houses were not set in gardens, and as a special amenity of urban life for certain classes and persons who desired a profitable leisure occupation and a "sense of contact with natural things." Their direct economic importance was greater in rural than in urban areas. The "field" allotments were definitely associated with the irregularity of employment or underpayment of labor in agriculture. In the north of England and in Wales, where farm workers were engaged on annual contracts, the allotment system did not develop. In these areas, as in Scotland, farm workers were commonly supplied with potatoes, or "potato-ground," as part of the conditions of employment. But in the greater part of the rest of England allotments were in demand, and in greatest demand where wages were low and employment irregular.

By 1880 fear of the possible independence of the laborer had passed, and some fear of the landless laborer and the capitalist farmer had arisen. The idea was then promulgated that allotments should provide one step in a rural social ladder and small holdings the next step, and from this time allotments and small holdings were associated in political discussions and programs. The maximum area of one allotment was subsequently raised to five acres. From 1882 the law relating to the public provision of allotments slowly developed, until in 1908 the Small Holdings and Allotments Act contained an elaborate set of regulations which were expected to make possible a provision whenever there might be a demand. In the meantime the conditions of agricultural employment had changed. The agricultural depression of 1879-1906 had finally driven out a surplus of population, and the adoption of machinery for harvesting processes had done much to equalize the demand for labor and to regularize employment for the workers who remained. On the other hand the social ladder had not developed extensively. By 1913 there was little demand for many groups of allotments in agricultural villages, and many individual plots were uncultivated. Where all were used the plots were grouped into larger holdings often occupied by persons who did not work for wages, and who did not always depend on cultivation as a main source of livelihood. In some cases an "economic climb" was begun with allotments, and erstwhile laborers became small holders or entered other occupations such as that of teamster. Individuals in special areas developed market gardening businesses on the basis of allotments. But before 1913 village field allotments were little more than subsidiary sources of income for agricultural workers.

With the strong demand for labor in the early period of the World War the cultivation of allotments was still more neglected, until in the spring of 1917 the potato famine and the fear of a general food shortage caused an almost frenzied rush to every possible source of food supplies. From then until 1919 practically all allotments in villages were fully cultivated, in spite of shortage of labor and rising incomes. Nearly all classes partook of this effort both in villages and towns. The Cultivation of Lands Order (1917) gave local authorities power to occupy uncultivated land and to let it as allotments. This order, amended and then substituted by

others, caused an increase of over 100 percent in the number of plots in cultivation. A total number of one million allotments was estimated to be in use at the end of the war. The pre-war number was probably 400,000, but no exact information is available. Societies of allotment holders had always been prominent in the urban movement, and these grew in numbers and activity during the war period. In rural areas societies were not so prominent, and it is probable that at least one half of the allotments in existence were let directly by owners of land to the individual cultivators.

In Great Britain the rural allotment system is essentially the result of the complete enclosure of common fields and wastes and of the consequent establishment of a class of landless workers. In other European countries land ownership is far more widely dispersed than it was in eighteenth and nineteenth century England; there is consequently no need for a public system of rural allotments. The distinction between a farm laborer and an independent agriculturist is usually not clearly drawn. Small holders earn a considerable share of their income as day laborers. Agricultural workers do not expect to remain dependent for the whole of their lives. Moreover they often enjoy the use of a cottage holding and of the employers' horses and implements as a part of their regular wage. Only in the twentieth century have certain governmental measures been taken for the settlement of the agricultural workers on the land. Such were the post-war provisions (preceded by enactments in 1907 and 1908) in Germany and the law of 1919 permitting local authorities to acquire land for laborers' cottage holdings in France. Cottage holdings in preference to detached allotments have recently found favor in England as well.

The urban allotment system had in its early stages pronounced utilitarian objects which were retained for a longer time in certain continental countries than in England. It is still primarily an economic arrangement in such countries as Belgium and the Netherlands, where industrial workers' families cultivate small garden plots in their spare time and thus provide variety in the family diet as well as some addition to the income. In Belgium the use of these garden plots is helped by low railway fare, which enables workmen to live where land is relatively cheap. It was of some economic and of undeniable psychological value in all of the belligerent countries during the war. On the

whole, however, the values attached to urban allotments at present are mainly sentimental, recreational and aesthetic rather than utilitarian.

ALLOWANCE SYSTEM. The allowance system became common in England toward the end of the eighteenth century. Its essential feature was a rate-borne grant in aid of the wages of able bodied workmen, often associated, as in the famous "Speenhamland Act," with a bread scale graduating the relief according to the price of bread. It laid down a minimum living wage which varied with the size of the family and provided such an allowance out of the rates as would bring actual wages up to this minimum. The system, intended as a temporary expedient to meet severe distress, became both widespread and long lived, lasting, despite much criticism, until the Poor Law Amendment Act, 1834. It was very general in rural England, and prevailed also in some manufacturing districts, such as the weaving areas of south Lancashire.

Criticism of the system, which has been held up as a warning against the policy of subsidizing wages, has continued for over a hundred years. Some of it is undoubtedly justified. In certain parishes the rates became inordinately high, and this imposed a heavy burden sometimes on leaseholders and often on landlords. Many employers took advantage of the system to pay a lower wage than they would

have done if it had not been enforced. But the view that outdoor relief in itself is vicious is largely discredited by the more humane attitude and fuller knowledge of today. When distress is widespread, it is futile to insist on granting relief only in certain institutions. There are not enough of them, and indoor relief costs more than outdoor.

Criticism has centered mainly on the variations of benefits according to the size of the family. Basing their arguments on certain moral presuppositions and assumptions, critics have arrived at a whole body of conclusions by purely a priori reasoning. They have argued that since the size of the family became a sure source of income, and a married man with children, or an unmarried mother of children, was better off than the childless man or woman, the system produced a rising birth rate. They have also contended that it was demoralizing—"that parental responsibility was discouraged, and that drunkenness, vice and crime grew apace." Recent research does not support this view. In some areas the birth rate was lower while the system was in force than in the succeeding period. From 1811 to 1821, while it was in full operation, the birth rate actually declined. But since identical fluctuations in statistics were observed in the non-Speenhamland counties no direct connection can be established. Perhaps the traditional melodramatic interpretation arose from the desire for a simple explanation of the degradation of the working class and the many evils of the early period of industrialism.

The new interest in the subject arises from the growing movement in a number of countries in favor of family endowment, for which the English "allowances" system constituted until recently the only available guiding experience.

ALMSHOUSE. In the United States this term denotes a public institution for indoor relief of the poor. This type of institution originated in England, where it is known as the workhouse; "almshouse" in England refers to the private endowed home for aged indigents. The English workhouse is conducted by a parish or a union of parishes, hence, colloquially, the "union."

The English Poor Law of 1601 authorized relief for the "impotent," the "setting on work" of the able bodied and the provision of "convenient dwellings" for the old and feeble. The act was not mandatory, however, and only a few workhouses or poorhouses were built. After many amendments of the law and much public discussion the first effective workhouse was built in Bristol in 1697. It was restricted to the able bodied who were given no relief elsewhere. Encouraged by the decrease of vagrancy and pauperism which ensued in Bristol, other cities followed suit. In 1723 a national act enabled all parishes, singly or in groups, to build workhouses, and provided that any individual refusing to be thus confined should not be entitled to other relief. This "house test" was based on the theory that the condition of the able bodied pauper must be made less desirable than that of the lowest paid independent laborer. In 1788 the notorious Gilbert Act authorized each parish or union to create a poorhouse for all classes of paupers except the able bodied, for whom the guardians were to find work near their homes and whose wages were to "contribute to their support." This system resulted in the lowering of wages, the demoralization of industry and the degradation of the laborers.

The Gilbert Act inaugurated the "mixed workhouse," which led to, and was so scathingly denounced by, the Royal Commission on the Poor Laws in 1832. The report of this commission advocated a return to the principles of the act of 1601, with the additional principle of segregation of indoor paupers, especially defectives and children, in separate institutions. Thus the evils of the workhouse system laid the groundwork for the modern programs for care of children, defectives and other special classes. The Poor Law Amendment Act of 1834 did not provide for complete segregation, but it did prescribe improved administration and created the Local Government Board as a central supervising authority. With considerable power to forbid, but little to compel, action, this board effected many reforms, although the gravest faults of the mixed workhouse continued.

In 1908 another royal commission found the more serious evils still unabated. While its majority report advised little more than better administration, a famous minority report declared that the conditions were so intolerable that nothing but a break up of the whole system could improve them, and recommended the extension of provisions of social insurance to relieve the prevailing abuses. However, even during the worst period of the mixed workhouse there were many exceptions to the usual conditions. Some buildings were so costly that they were nicknamed "palaces for paupers." Some boards of guardians were intelligent, public spirited and sympathetic, and a few wardens and matrons were efficient and humane, but these were exceptions to the general rule.

In the United States the word almshouse is the generic term for public institutions for poor relief, but the actual names of such institutions vary according to locality. Thus although almshouse is the legal name in New England and is fairly consistently found in the East and South, in Ohio it is "infirmity"; in Indiana, "asylum"; and in the Middle West, "poorhouse," "poor farm," "county farm" or "county home." In California the county hospital has a department for the non-sick paupers, and in New York City there is a Home for the Aged and Infirm.

In the New England states, with the exception of the county almshouses of New Hampshire (which are also houses of correction), the state almshouses for the unsettled poor of Massachusetts and Rhode Island and a city almshouse in Boston, the almshouses are conducted by towns. In New Jersey there are county, township and municipal almshouses. Pennsylvania has five classes: county, township, township district, borough and municipal. In Virginia district homes are replacing county almshouses. Some cities conduct large institutions. In some states there are counties with almshouses and others in which the plan of letting out the care of the poor by contract, at one time a very common practise copied from an English law of 1723, still persists. New Mexico has no almshouses. Everywhere else the county almshouse prevails.

The almshouse was the first and for many years the only public charitable institution. The colonies copied English laws and practises, and at first, as in England, the care of the poor was connected with the church; some of the earliest laws provide for the support of both the poor and the parson. Attempts to combine relief of the destitute with labor for the unem-

ployed are noticeable even to the present day, and the term "Work and Poor House" is frequently found. Many states have laws requiring that able bodied inmates be kept at work. The early almshouse was often used as a house of correction. Later the states again followed England in the appointment of commissions for the study and improvement of conditions.

The inmate population of a present day almshouse may vary from three or four in a small town almshouse to 2500 or more in a large city institution. Some of the largest are conducted with economy and reasonable comfort, with departments for the sick and defectives, and a few with special provision for the better class of inmates. Some small almshouses are conducted like a farm home where the inmates are regarded as one big family. The cottage plan in the more modern almshouses, as in other public institutions, approximates these conditions for the large almshouse. In some places today, although less frequently than before, one finds almshouses where the cost is inordinate and the conditions abominable: old and young, feeble and strong, sick, insane, epileptic, idiotic, sometimes even male and female, herded together in squalor, neglect and vice. Wherever the standard of living of the laboring people is low, the standard of the almshouse is lower. There is little relation between the cost per capita and the comfort and decency of the accommodations; some of the worst conducted almshouses are among the most costly. There are instances where the number of employees is greater than that of the inmates. In 1924 there were 137 almshouses without inmates, many of them with employees on the pay roll. The quality of almshouse administration depends on the superintendent, who is rarely of superior ability, since local party politics often controls the selection of officials. Jobs are needed to reward party workers with each political shift, so that even with the best intentions the almshouse superintendent hardly learns his work before he is superseded. It is evident that, with no special ability or training among the officials, inmates requiring skilled treatment are neglected.

There are, however, provisions in many states for the specialized care of the insane and imbecile and for dependent children in most. The tendency, characteristic of contemporary case work, to emphasize the importance of family solidarity rather than economy of care results in the limitation of the almshouse population to the indigent aged, at least in sections

where case work standards are highest. One alternative to almshouse care is outdoor relief, for which there are many requests from people who refuse to go to the almshouse. A second alternative is old age pensions and other forms of social insurance, which prevail in England and on the continent, but which have not yet been developed in the United States to any appreciable degree, although the prospect for old age pensions is now good.

Varying in different states according to the state provision for the class, from one fifth to one half of almshouse inmates are mental defectives, and these are usually the best inmates from the administrative point of view. There are well conducted almshouses wherein all the domestic and farm labor is performed by imbeciles or by harmless, chronic insane. On the other hand it is impossible in the ordinary almshouse to give adequate protection to imbecile females of child bearing age, and no state has yet made adequate provision for them, with the serious consequence that many imbeciles are by-products of almshouse care.

County almshouses are usually on farms, because of the supposed economy of raising one's own food supplies. There are rare instances in which the sale of surplus products has defrayed the cost of the institution. But as there is usually little available inmate labor, many farms are run at a loss. Of the 350,000 acres of farm land occupied by almshouses in the United States little more than half is utilized, and much of that poorly.

These and other unsatisfactory conditions have long been recognized, and many laws for regulation and improvement have been enacted. In most states standards are advancing. Many states have regulations forbidding the housing of children among paupers, although the laws are often disregarded. In states having boards of public welfare, almshouses are inspected and supervised. Although such boards, with rare exceptions, have no mandatory powers and depend on persuasion and publicity, much improvement is due to their efforts. In a few states county boards of welfare have been able to improve conditions by enlisting the force of public opinion in behalf of better county management. Eighteen states have enacted laws for the consolidation of county almshouses into district homes serving a larger area, and in the few states where this plan has been put in operation improved standards of care and financial economy have resulted. In Virginia the

saving has been over fifty percent. But merely increasing the size of the group will not remedy all present evils. Better and more general social welfare work and more efforts at prevention are needed. With all the best governmental machinery that can be devised, there will still remain the need of educated public opinion which shall demand that the almshouse be made exclusively a home for the aged and infirm.

ALSACE-LORRAINE. For a thousand years or more Alsace-Lorraine has been a cause of controversy and war to the dwellers on both sides of the Rhine. By the division of Charlemagne's empire among his three grandsons at Verdun in 843, Alsace and Lorraine fell to Lothair, and were included in his kingdom of Lotharingia; this name, in its French form, Lorraine, has adhered ever since to a small part of Lothair's inheritance. During the Middle Ages Alsace-Lorraine formed part of the Holy Roman Empire and became split up into

numerous small counties, bishoprics and "free cities." The bishopric of Metz was conquered by Henry II of France in 1552, and formally ceded to France by the Treaty of Westphalia in 1648. Most of the surrounding Lorraine territory was transferred by its Hapsburg ruler to Louis xv's father-in-law in 1735, and joined to France in 1766. Alsace was acquired by Louis xiv, partly by French conquests in the Thirty Years' War and the ambiguous terms of the Treaty of Westphalia, partly by the forcible seizure of Strasbourg in 1681, and partly by claims and conquests which were confirmed by treaty in 1697.

At the time of their transfer to France the populations of Alsace and Lorraine were strongly bound by cultural ties to Germany, being German in habits, institutions, feeling, and almost wholly in language. This was especially true of Alsace where Strasbourg, Colmar and other towns had played a leading part in the literary and artistic life of Germany. But Louis xiv and his successors so respected the local rights and privileges of the inhabitants that the change in sovereigns was not greatly resented. Although the French language had to be used in the law courts and made progress among the upper classes in the towns, local affairs continued very much in the old way and in large measure in the German language. Thus the period from 1648 to 1789 was largely one of gradual and painless assimilation.

The French Revolution accelerated this assimilation process. It put an end to mediaeval German social and political conditions, reorganized Alsace and Lorraine into three new French departments, and introduced a democratic social and administrative system uniform with the rest of France. In spite of local resentment at the antireligious legislation of the government at Paris, Alsace and Lorraine in general welcomed and shared enthusiastically the work of the revolutionary and Napoleonic era. The *Marseillaise* was composed and first sung at Strasbourg, and Alsatians served in great numbers in Napoleon's victorious armies. Alsace-Lorraine became a living part of the French body politic, and so remained until the Franco-Prussian War.

Bismarck's annexation of the provinces in 1871 was dictated primarily by strategic considerations. His generals insisted that the German possession of Metz, and the establishment of the Vosges instead of the Rhine as the boundary, were necessary to the future safety

of the new German Empire against a possible French war of revenge. Bismarck openly stated that the region was to be a glacis against a possible French attack. His action was further justified on the ground that he was "liberating" territory which had been wrested from Germany by Louis XIV at a time when Germany was weak and divided against herself. But there was a vast difference between the French annexations in the seventeenth century and Bismarck's annexation in 1871. Between these two periods lay the French Revolution and the forces to which it had given rise. Nationalism, popular education, universal military service and the greater activity of the state in relation to the individual made a transfer of sovereignty a far more important matter for a people in the nineteenth than in the seventeenth century. Louis XIV in seizing Alsatian districts did not dismember Germany, because there was at that time no united German body politic—nothing but a conglomeration of mutually jealous German territories. The so-called Holy Roman Empire was "neither Holy, nor Roman nor an Empire," but, as the German Pufendorf said, "an irregular sort of body like a monster," incapable of feeling a wound. The French Revolution, however, in sweeping away provincial boundaries, had created a new self-conscious nation, "one and indivisible." France, including Alsace and Lorraine, had become one body, powerfully conscious of its unity and nationality; if one of its members suffered, all suffered together. Bismarck mutilated a living body, and the wound would not heal; it remained to threaten the peace of Europe for forty years. It also gave rise to the fatal system of alliances which came to divide the Great Powers of Europe into two hostile groups, and which was one of the main causes of the World War.

If Bismarck had immediately granted the annexed provinces, or "Reichsland," a large measure of autonomy, with careful regard for local privileges and feelings, it is possible that their resentment at being annexed might have gradually died away after a generation of material prosperity. If he had dignified their position by making them one of the component states of the empire, with a democratic legislature and representation in the Bundesrat, on equal terms for instance with Saxony or Baden, they might have become reconciled to the transfer of sovereignty. But, instead of this, Prussia imposed a military regime, which was

regarded as severe and oppressive, and which fed the fire of discontent and protest both in Alsace-Lorraine and across the border in France.

Germany made many efforts to win the allegiance of the annexed provinces. Mediaeval castles were rebuilt to give employment and to flatter local pride. German immigrants took the place of natives who preferred to emigrate and live in France. Railways and factories were built. Potash deposits in southern Alsace were unearthed and developed to such an extent as to give Germany the leading world position in an industry of great importance for agricultural fertilizers and the chemical trades. Petroleum was tapped and exploited in considerable quantities at Pechelbronn in northern Alsace. In Lorraine the production of coal, and especially of iron, was accelerated to an astonishing degree; the iron of Lorraine and the coal, coke and steel mills of the Ruhr were rapidly developed as a natural and necessary economic unit. But in spite of these efforts the undercurrent of discontent flowed on. The grant of limited autonomy and representation in the Bundesrat, which was finally accorded to the Reichsland in 1911, came far too late, and did little to improve the situation.

The World War gave France her long awaited opportunity to recover the lost provinces. None of her responsible statesmen had seriously planned to provoke war simply to recover the territory lost in 1871; but, once the World War broke out, France instantly insisted on the restitution of Alsace-Lorraine as one of the absolute and unshakable conditions of peace. Germany's long continued refusal to consider such a condition wrecked various peace efforts, and tended to prolong the war. But finally Germany, defeated in the field, in order to secure an armistice had to accept President Wilson's Fourteen Points, one of which stated that "the wrong done to France by Prussia in 1871 in the matter of Alsace-Lorraine . . . should be righted." Accordingly the Treaty of Versailles restored the two provinces to France as a matter of right. Elaborate provisions were made, however, to protect the interests of German immigrants and to prevent a too sudden rupture of the economic bonds which had gradually united Alsace-Lorraine to Germany.

The spontaneous enthusiasm which greeted French troops upon their entry into Alsace-Lorraine at the end of the war was eloquent

evidence of the French sympathies of the population. But in the decade 1919 to 1929 this enthusiasm waned. During the half century of German rule Alsace-Lorraine had grown accustomed to a decentralized administration and to being treated as a unit; the French have a highly centralized administration and again divided the region into three departments. The government at Paris has paid small heed to local prejudices and to the desires of the restored population. This is particularly true in religious, school and labor problems. Since 1905 France has been living under laws which separate church and state and which prohibit religious instruction in the schools, but Alsace-Lorraine still abides by Napoleon I's Concordat with the papacy (see ANTICLERICALISM). Nearly four fifths of the Alsatians are Roman Catholics, and for the most part devoutly religious. Communist propaganda has been carried on against Parisian capitalists. The situation is indicated in the paradoxical statement: "The Alsatian laborer is a Communist who attends mass every Sunday." Under these various influences a strong autonomist movement has developed in Alsace, signified by the arrest in December, 1927, of twenty-four Alsatians charged with conspiracy to overthrow the existing regime.

In view of the Locarno Treaties of 1925, guaranteeing the existing frontier between Germany and France, it is to be hoped that Alsace-Lorraine has at last ceased to be a cause of controversy and a danger to the peace of Europe.

ALTENSTEIN, KARL, FREIHERR VON STEINZUM (1770-1840), Prussian minister of education. After holding several political offices, including that of minister of finance (1808-10), he was placed in charge of the Ministry of Ecclesi-

astical, Educational and Medical Affairs in 1817, when it became an independent department separate from the Ministry of the Interior. His accession to this office coincided with the beginning of the reaction under Friedrich Wilhelm III. Although well intentioned, Altenstein lacked practical ability and was unable to put into effect the far sighted educational program drafted by Süvern in 1819. His period of office, which lasted until 1838, was marked by the consolidation of the school as a political agency and the establishment of a strong bureaucracy, possibly under the influence of his friend Hegel, who joined the University of Berlin in 1818. Largely through Johannes Schulze, who assumed charge of secondary and higher education in 1818, a return was made to the tradition of the sixteenth century with an emphasis on classics and religion, and the *gymnasium* was recognized as the only secondary institution preparing for the universities; all movements of a realistic or practical tendency were checked, and strict requirements were enforced for the certification of teachers and the control of their political views. Progress was made in the training of elementary teachers, mainly because the normal schools were left undisturbed until after the Revolution of 1848. In elementary education Altenstein adopted the view of Friedrich Wilhelm III that it must not raise the masses out of the sphere designed for them by God and society, but must make their lot happy and agreeable. Altenstein retired from the ministry two years before his death.

I. L. KANDEL

ALTGELD, JOHN PETER (1847-1902), governor of Illinois from 1893 to 1897. He became nationally prominent because of his pardon of the three surviving "anarchists" convicted of complicity in the Haymarket bomb case, his protest to President Cleveland against the sending of federal troops to Chicago during the Pullman strike, and his part in the free silver campaigns of 1896 and 1900. For his pardon of the anarchists he was subjected to vilification and misrepresentation rarely, if ever, equaled in American public life.

Altgeld was born in Germany and brought to America as a child. After studying law and serving as county attorney in Savannah, Mis-

souri, he went to Chicago in 1875, made a fortune in real estate, and served from 1886 to 1891 as a judge of the Cook County Superior Court. As governor he was a pioneer in mild social and political reforms, vetoed bills giving long franchises to Chicago public utilities, suppressed graft and inefficiency in public offices, greatly improved the penal and charitable institutions of the state, and raised the University of Illinois from a comparatively insignificant small college to an honorable position among educational institutions. The reform measures passed during his administration and with his aid include a civil service law, an inheritance tax law, a law providing for indeterminate sentence, parole and probation for prisoners, another regulating the sweating system and child labor, limiting the hours of women workers to eight a day and providing for factory inspection, and still another establishing a state board of arbitration for industrial disputes. He was also a pioneer in appointing women to public offices.

Consult: Browne, Waldo, *Altgeld of Illinois: A Record of His Life and Work* (New York 1924); Masters, E. L., "John Peter Altgeld" in *American Mercury*, vol. iv (1925) 161-74.

ALTHUSIUS, JOHANNES (1557-1638), political theorist and jurist. After studying law and philosophy at Basel and possibly Geneva, he held a professorship (with minor interruptions) at Herborn in Nassau until 1604. In that year he became syndic of the town of Emden in eastern Friesland, a prosperous trading center. He was an ardent Calvinist. He wrote several works on legal matters, particularly a widely used general treatise on Roman law; he was the author also of a little tract in the humanistic tradition on polite manners.

His main work, however, is the *Politica methodice digesta atque exemplis sacris et profanis illustrata* (Herborn 1603, enlarged 2nd ed. Groningen 1610, still further enlarged 3rd ed. Herborn 1614). This is (according to Gierke) the first systematic treatise on politics since the ancients. Its express purpose is to bring political science into accord with Calvinist theology generally, and particularly to apply the teachings of the Old Testament to a further development

of Aristotelian politics. Indeed his work may be considered as the most developed system of politics which Calvinism has produced. But if the general ideas are supplied by Calvinist theology, the context of experience is to be found in the complex life of central European political communities, woven into the tenuous pattern of the Holy Roman Empire of the German nation. In fact the *Politica* may from this point of view be described as a systematization of the political ambitions represented by the craft guilds throughout the preceding two centuries in their efforts to democratize the town government, as well as of the similar political ambitions of the towns themselves in their struggle with the territorial princes. Unlike the writings of the monarchomachs with which it is commonly classed, the work of Althusius is not propagandist in nature. Quite on the contrary, it was the doctrines expounded by him that drew him into practical politics. His reasoning is based upon a strong philosophical individualism tempered by a profound appreciation of the individual's dependence upon a variety of groups. He emphasizes time and again the fact that the justification of all groups is to be found in their ability to provide a *vita beata, commoda et felix* for its members. The repeated emphasis upon the *vita commoda* and the further elaboration of this idea foreshadows Bentham's pleasure calculus and the doctrine of the utilitarians. Nevertheless there is a strongly puritanical note in his concept of comfort. Within this limitation there is a spirit of distinct worldliness permeating the entire work, which becomes apparent, for example, in the author's reasoned preference for the *vita activa* as against the *vita contemplativa*.

Althusius' fundamental attitude toward life is in harmony with his exposition of popular sovereignty as a desideratum. But his theoretical genius appears in the way he deals with Bodin's doctrine of sovereignty. He accepts Bodin's theory that sovereignty is in its nature indivisible; but for precisely the same reason he claims that sovereignty is an essential condition of the existence of the political community and therefore cannot be surrendered by the people to anyone. As Gierke has pointed out, Althusius clearly produces the argument with which Rousseau almost two hundred years later set the world on fire. Similarly Althusius develops a complete theory of the social contract. Popular representation is also a well defined part of his system, but he insists upon the superiority of

the primary assembly. In order to overcome the difficulties which such a preference for direct democracy involves, he introduces the concept of a complex federalization and integration of the several smaller units into a manifold hierarchy of authorities. The component corporate units are supposed to have a life of their own of which they transmit to the higher unit only enough to enable it to fulfil its specific purposes, all of which are dictated by the interests of these smaller units. This aspect of his thought has made a particular appeal to the modern pluralists, who are inclined to consider him as one of their forerunners.

Althusius aroused much interest during his lifetime and in the decades following, and his doctrines were widely discussed, praised and condemned. But with the ascendancy of absolutism on the continent interest in them waned. It was left to Gierke to rediscover him in connection with his extensive researches into the nature of the corporation and what he termed the Germanic concept of corporation.

CARL JOACHIM FRIEDRICH

Consult: Gierke, Otto von, *Johannes Althusius und die Entwicklung der naturrechtlichen Staatstheorien* (3rd ed. Breslau 1913); Wolzendorff, Kurt, *Staatsrecht und Naturrecht in der Lehre vom Widerstandsrecht des Volkes gegen rechtswidrige Ausübung der Staatsgewalt* (Breslau 1916) p. 198-247.

ALTRUISM AND EGOISM. The term altruism, in its psychological sense, means the disposition of an individual to further the welfare or happiness of other individuals or groups. Egoism is the contrary disposition to further one's own welfare or happiness. The ethical theory of altruism assumes that the altruistic disposition is at least of coordinate psychological standing with egoism and that as a matter of ethics it should prevail over egoism in cases of conflict. Ethical egoism reverses the second part of this statement and is inclined on the whole to deny the indicated psychological assumption also.

Seventeenth and eighteenth century British moralists argued at length the psychological genuineness of altruism or benevolence. The religious and civil disturbances of the seventeenth century had brought to definition the self-conscious individual as the unit of social grouping and organization. In England, as on the continent, though with a different emphasis, the basic characters, the powers, rights and possibilities of the individual were the themes of political and moral philosophy. Much as

Hobbes (*Leviathan*, 1651) deprecated the inordinate excesses of individualism, he never questioned the standing of the isolated individual as the true unit of political organization. For Hobbes the individual is fundamentally egoistic. Pity, he declares, is nothing but "imagination or fiction of future calamity to ourselves, proceeding from the sense of another man's calamity," and love, good will or charity, a mere pleased conceit of one's power to "assist other men in their desires." Mandeville (*Fable of the Bees*, 1723) held that only by artfully "extolling the excellency of our nature above other animals" had law givers been able to "persuade mankind to disapprove of their natural inclinations or prefer the good of others to their own." In opposition to this egoistic conception of the individual, British moralists, from the seventeenth century to J. S. Mill and Sidgwick, were essentially agreed that there are in human nature disinterested benevolent impulses and social sympathies as certainly genuine and native as the self-regarding.

The right relation of these two groups of impulses was, however, a perennial problem. For Joseph Butler (*Fifteen Sermons*, London 1726, no. iii) self-love must be held in check by conscience in order that a right balance of self-interest and the welfare of others may be assured. "In the common course of life there is seldom any inconsistency between our duty and what is called interest." When there is such inconsistency, conscience must prevail. For Sidgwick, (*Methods of Ethics*, London 1874, bk. iii, ch. xiii) what Butler calls conscience becomes a rational intuition to the effect that "the good of any one individual is of no more importance from the point of view of the universe than the good of any other," and that "as a rational being, I am bound to aim at good generally, not merely at a particular part of it." Neither Butler nor Sidgwick, in this reliance on a transcendental factor, has Bentham's faith in the adequacy of mundane or supernatural penalties and rewards to make socially expedient behavior appear to the intelligent individual a good bargain (*Introduction to the Principles of Morals and Legislation*, London 1789, ch. iii), or Mill's assurance that "the deep rooted feeling which every individual even now has of himself as a social being" must of itself make it impossible for those whose minds are not "a moral blank" to "lay out their course of life on the plan of paying no regard to others except so far as their own private interest compels" (*Utilitarianism*, London 1864, ch. iii).

So long as the problem is stated in the traditional terms of separate groups of impulses set side by side in rivalry in human nature, solutions must, as history shows, be ambiguous and inconclusive. However, a strictly self-seeking egoist, with no disinterested thought whatever for any other persons besides himself, is a monstrosity. So-called selfish persons commonly if not always include within the scope of the "social self" (William James, *Psychology*, 2 vols., New York 1890, vol. i, ch. x) a considerable number of other persons—parents, children, relatives, friends, compatriots—whose interests they put above those of the larger body of society. The perfect egoist is at best the limiting case, seldom if ever actually encountered. Egoism is in fact not so much the preferring of one's own well-being to that of others as refusing to widen the scope of one's interest in other persons in order to include claimants who think themselves wrongfully ignored. A man may deal hardly with others in trade or as an employer and yet very probably expend his gains for the pleasure of his family or friends with little or no direct participation on his own account. He deserves to be called an egoist, but chiefly because of the unimaginative inertia with which he resists any change in a way of living to which he has become accustomed. The egoist habitually cleaves fast to his established and congenial manner of life or system of values as against appeals made in behalf of others to change it. The altruist is normally or characteristically responsive to such appeals. The ultimate aim of both may be "happiness," but the difference between the ways by which egoists and altruists seek ultimate happiness loses nothing whatever of its social importance, even on such a showing (cf. Sidgwick, *Methods of Ethics*, bk. ii, ch. i).

Egoism has been widely if not generally believed to be the foundation postulate of economics. Economic theory has been regarded as essentially an account of egoism in action, with altruism playing the part of a more or less stubborn and disturbing intruder. This view seems confused and unnecessary. The analysis of the situation defining the market price of a commodity, for example, need take no account of the reasons lying behind the personal demand prices and supply prices of the commodity. All manner of aspirations, ambitions, curiosities, inhibitions, darings, cautions, stupidities, egoisms and altruisms are overtly expressed in the valuations of the several participants in the market equilibrium. On these valuations the eventual market

price depends. If, now, an analysis in terms of the participating valuations is deemed worth while, it is because, on the whole, the situation is not expected to change in respect of them within a measurable period. It is assumed merely that buyers and sellers know their minds, by whatever logic and psychology made up, and that, apart from influences looking to the alteration of their motives, few if any of them will find it expedient, from their points of view, to change their valuations. In all this there is no implication of the priority or predominance of egoism over altruism in human nature. The theoretical analysis is the same, whether philanthropists, self-seekers or persons combining both qualities make up the market. Perturbations of the ideal smoothness and symmetry of market adjustment come not from irruptions of altruism as such, but from guess work, blundering and indecision.

As Locke sought to vindicate the immunity of the individual, in natural right, from civil and religious tyranny, so the British economists of the next century sought to justify the individual's freedom from governmental interference with his gainful pursuits. The economic man was the free citizen of Locke entering upon the affirmative exercise and enjoyment of his freedom (cf. *Robinson Crusoe*, 1719), not essentially or necessarily an egoist. His determination to make his way in the world has exposed him to some misrepresentation at the hands of both his abettors and his critics. It is not this determination that makes him egoistic when he is so, but a too lively fear of changes in law and social conditions that may put him to the cost and trouble of redefining it.

Thus the definition of egoism (and of altruism) given at the outset represents the point of view of an outside observer, not that of the agent himself. When other individuals or classes of individuals are adversely affected by my "unimaginative inertia," the fact is outwardly patent. I shall be reproached with "selfishness," whereas from my own point of view my shortcoming is not different in kind from falling into a rut in any other respect, as, for example, in my intellectual or aesthetic interests or in my friendly associations. Conversely my life may be freshened and invigorated not only by diversifying my privately personal interests (about which no one else has much reason for concern) but by actively interesting myself in the welfare of other persons (who are quite likely to notice the fact and to pass judgment on the

measure of my success). Thus the old problem of the genuineness of altruism and its ability to withstand or right to put down egoism becomes obsolete today. The real problem is the balancing of habit and initiative in the individual's conduct. Thus the supposed psychological priority of egoism over altruism disappears.

ALVAREZ, AGUSTIN (1857-1914), Argentine political ethicist and sociologist. He was graduated from the national military college in 1878 and received his doctorate in law from the University of Buenos Aires in 1888. He saw military service on the frontiers, rose to the rank of brigadier general and was secretary of the supreme council of the army and marine (1896-1906). He taught international law in the national military college (1904-14) and was professor, vice president and acting president in the University of La Plata at various times after 1906. His chief work, however, was that of critic of Latin American institutions. A disciple of Emerson and Sarmiento, he applied the penetrating social criticism of the former and the energetic analysis of the latter, reenforced by his own sterling independence and honesty of character, to an evaluation of the social inheritance of the Spanish American civilization, particularly with respect to religion and politics. He held up always to the view of his fellow countrymen the example of Anglo-Saxon institutions, which he greatly admired. But his criticism was meant to cure rather than to wound, and his teachings have been greatly admired by his fellow Argentines.

L. L. BERNARD

Important works: *South America* (Buenos Aires 1894); *Manual de patologia política* (Buenos Aires 1899); *Ensayo sobre educación* (Buenos Aires 1901); *Adonde vamos?* (Buenos Aires 1904); *La transformación de las*

razas en América (Buenos Aires 1908); *Historia de las instituciones libres* (Buenos Aires 1909); *La creación del mundo moral* (Buenos Aires 1912).

Consult: Colmo, Alfredo, *Principios sociológicos* (Buenos Aires 1905); also the biographical introductions to Alvarez' works in *La Cultura Argentina* edition.

ALVORD, CLARENCE WALWORTH (1868-1928), American historian. He was born in Massachusetts and received his advanced training at Berlin and at the University of Chicago. He taught history at the University of Illinois, 1897-1920, and the University of Minnesota, 1920-23. Having discovered and edited the *Cahokia Records* (Springfield 1906), relating to a French settlement in Illinois during the American Revolution, he was made general editor of the *Collections* of the Illinois State Historical Library; and the fourteen volumes of the series issued (1907-20) under his editorship set a new standard for state historical publications, as did also the *Centennial History of Illinois* (5 vols., Springfield 1918-20), of which he was the editor. He was influential in shaping the policies of the Mississippi Valley Historical Association, brought about the establishment under its auspices of the *Mississippi Valley Historical Review* in 1914, and served as its editor until 1923. His most important writings are *The Illinois Country* (Springfield 1920) (vol. i of the *Centennial History*) and *The Mississippi Valley in British Politics* (2 vols., Cleveland 1917), which received the first Loubat prize. Alvord's work is notable for its thoroughness, accuracy, objectivity and literary quality. Its importance is not to be gauged by the fact that most of it was in the field of state history; it did much toward a reorientation of emphasis upon the mid-western aspects of American history. The last four years of his life were spent largely in England, where he was honored with important lectureships.

OLON J. BUCK

Consult: Buck, S. J., "Clarence Walworth Alvord, Historian," with a bibliography of his published works, in *Mississippi Valley Historical Review*, vol. xv (1928) 309-20, 385-90.

AMALGAMATION is the biological union of previously distinct racial groups. There are three major stages in the process: first, cross breeding of divergent stocks to the production of a mixed-blood population; second, isolation and selective adaptation of the hybridized stock; and third, the ultimate establishment of a distinctive racial strain.

The contact of racial groups seems everywhere to result in some degree of amalgamation. The skeletal remains of early man show unmistakable evidence of racial intermixture. The populations of the modern European nations are in every case composed of diverse and incompletely fused ethnic elements. In the recent centuries, as a secondary consequence of world commerce and colonial policy, there has been an extensive crossing of racial stocks previously little in contact. Typical of these are the mulattoes in the United States, Brazil and South Africa; the Indian-white and Indian-Negro mixtures of both Americas; and the Eurasians of the Asiatic coast cities.

The biological effects of race crossing are difficult to determine because of the multiplicity and complexity of human characters and because of the hybridity of the modern races. In general the results are in accord with genetic principles that prevail in the hybridization of other forms of life. Certain traits are transmitted in accordance with a simple Mendelian formula. But the great majority of human characters are the result of multiple genetic factors. Consequently, there is a marked tendency toward blending, and the hybrid offspring approximate an intermediate type with, however, the reappearance in successive hybrid generations of certain ancestral traits. The Darwinian belief that race crossing leads to increased vitality and fertility and the opposed belief that it results in sterility and racial degeneration appear, in the light of modern knowledge, to be equally unfounded. Each rests upon partial data and upon the failure to disengage the exact cause or causes of the superiorities or inferiorities observed. The biological effects of racial crossing depend upon the hereditary constitution of the individuals generating the cross breeds, and are quite independent of the racial stock.

Racial amalgamation is related as both cause and effect to social assimilation. Biological intermixture, by increasing the number and intimacy of social contacts, promotes the fusion of social heritages and the diffusion and blending of cultures. On the other hand the social and psychological similarity resulting from cultural assimilation favors intermarriage through increasing mutual understanding and personal appreciation.

The crossing of races has other sociological consequences of far reaching significance. The hybrids may be identified with either parent

race or form an intermediate caste; the specific adjustment depends upon the race and caste prejudice of the culturally dominant group. In any case they occupy a strategic position: they function as a buffer between the racial extremes and play the role of cultural mediators and interpreters. The mixed-blood individuals are often cultural as well as racial hybrids. They stand between two civilizations without being fully incorporated into either, and manifest in their personality characteristics the same fundamental cultural conflict that characterizes the bi-racial situation.

AMANA SOCIETY. See COMMUNISTIC SETTLEMENTS.

AMARI, MICHELE (1806-89), Sicilian patriot and historian. His early education and preparation reflect the peculiar political conditions of Sicily, where the struggle for liberty took the form of an endeavor to reestablish a separate kingdom. Amari espoused this cause and contributed to its furtherance by publishing in 1842 *Un periodo delle istorie siciliane del secolo XIII* (8th ed. Florence 1876). This innocent title masked a powerful arraignment of the Neapolitan rule and of its basis in the claim of the historic unity of the Two Sicilies.

The publication of this book forced him to leave Sicily. He took refuge in Paris, where he remained until 1859, except for the year he dedicated to active and courageous participation in the Sicilian revolution of 1848. At Paris he made himself a master of Arabic language and culture, published many scholarly articles, edited and translated important works and gathered material for his great work on the mediaeval history of Sicily. The nature and extent of his researches can be seen in the scholarly and comprehensive collection which bears the name of *Biblioteca Arabo-Sicula* (2

vols., Leipsic 1851-75), published by the Oriental Society of Germany; they constitute the foundation of his monumental work, *Storia dei Musulmani in Sicilia* (3 vols., Florence 1854-72). This work gives a documented description of the civilization which the Moslems created in Sicily, of the conditions that preceded it, and of its persistence in later times. It appraises the contributions of the Normans and proves how in reality it was "Italy that under their leadership took possession of the island." It is a classically written and scientifically motivated description of the converging results of four civilizations and of the interaction of their arts, sciences, traditions and religions.

In 1859 Amari returned to Sicily, took part in the Garibaldi government and, no longer a Sicilian separatist or a federalist or even an Italian republican, he became a senator of the kingdom, minister of public instruction (1862-65), and professor of Arabic language and history at Florence. Amari's writings mark the transition from controversial and patriotic historiography to purely scientific inquiry. He never lost his patriotic passion, but his scientific instinct enabled him to discover the proper object for his political ardor. No one in the nineteenth century had more influence than he in founding in Italy a school of historiography based on original documents and on the criticism of sources.

(Turin 1896) vol. ii, p. 315-97; Derenbourg, Hartwig, "Carteggio di Michele Amari" in *Journal des Savants* (1902) 209-22, 486-98, 608-22; Croce, Benedetto, *Storia della storiografia italiana*, 2 vols. (Bari 1921) vol. ii, p. 28. A complete bibliography of Amari's works is to be found in the *Centenario della nascita di Michele Amari*, 2 vols. (Palermo 1910) vol. i, p. xlv-cviii.

AMATEUR. The amateur is one without professional training or experience who engages in something solely because he enjoys doing it. In an evaluation of his status in society he must be understood not as the opposite of the professional but as his complement. There cannot always be a tenable distinction between amateur and professional since the latter's position itself is usually undefined; it may rest on such tenuous considerations as the conventions of the period, the quality of his work, his measure of success, or his estimate of himself, and he may be equaled by the amateur in some of these respects. Nevertheless amateurism in gen-

eral may be said to mean the pursuit of a subsidiary interest, not primarily for a livelihood, in imitation or appreciation of something already done by a skilled worker.

There are many activities which are not to be classed as either amateur or professional. They derive from impulses and necessities that are everywhere existent, and are the origins from which professionalism, and ultimately the amateur's imitation, develop. When such pursuits are professionalized they are still not by any means given over entirely to specialists. Though there are professional cooks and entertainers, the housewife and the hostess are not thereby rendered amateurs. They are rather the precursors of both.

The appearance of the amateur is necessarily preceded by specialization and the recognition of specialists. Primitive and folk arts cannot be considered amateur activities. Specialization often exists in primitive communities, but only in certain activities, such as blacksmithing or carpentry or priestcraft, and these are recognized as the province only of certain persons. The economic organization does not permit of imitation merely for the sake of personal pleasure. Where the arts are participated in by the entire community, where each man fends for himself or all share alike in the provision of shelter, food and recreation, the results may appear amateurish in relation to other standards, but in that community the distinction does not exist.

Amateurism holds a different emphasis according to the group or period in which it appears, and its extent and direction depend on many variables. Until modern times the privilege of leisure time interests has been limited to the aristocracy. Since activities essential only for self-satisfaction and not for livelihood are something of a luxury, the amateur cannot appear in periods or classes where maintenance dominates life. Hard working communities have their recreations, but when time is short these are likely to take the easier, less intellectual form of games or entertainments provided by others instead of the more deliberate individual effort which amateurism involves. Moreover some educational background is necessary—a recognition of those things that exist beyond the daily routine of experience. Some appreciation of arts and of crafts is necessary to inspire imitation of them; knowledge and developed sensibilities are necessary to permit appreciation.

The leisured classes, therefore, have con-

tained the amateurs. The later days of the Roman Empire, the Italian Renaissance, Elizabethan and Caroline England, the court of Louis XIV, were vibrant with a polite imitation of the arts which was often amateurism of the finest kind. The lack of respect for the professions made amateurs of a great many persons of talent who today would candidly follow their interests as occupations. The tradition of aristocracy that its members shall not earn a living by their own efforts puts in bad repute, as long as aristocracies set the fashion, any pursuit that is followed professionally. A nobleman poet, therefore, who writes apparently only for his own pleasure and to follow the vogue of the time, denying even that he is the author of his verses, may rightly be considered an amateur, but if he prove to be a Philip Sidney it is apparent that he is an amateur only because of the conventions of the time.

By the eighteenth century the ideals of aristocracy had largely lost their hold, and professions had begun to be acknowledged as desirable. The artist was released from the rigors of patronage and the man of talent was able to follow his interests with independence and respect. The elegant amateurism of the nobility, which had not only resulted from leisure and fashion but had also contained the professional interests of the upper classes, gave way therefore to forms at once more imitative and more democratic. This shift in emphasis entailed a closer definition of occupations. New knowledge began to convert eclecticism into neat professional patterns. Instead of a Francis Bacon, with a knowledge of all fields, there appeared the chemist, the physicist, the mechanic, the physician, the man of letters, each a professional in his own field and an amateur outside it. Enthusiasm was high for the new ideas and discoveries, and in a period of such stimulation amateurism is one of its expressions. Social intercourse rested largely on an interplay of minds, and institutions arose which fostered this ideal. The salons of the eighteenth century, the coffee clubs, the earnest Bluestockings, bred by the score amateur writers and critics, philosophers and political theorists. A stimulus and a focus were offered for the expression of interests which would not, or could not, be followed professionally and which were given birth by the increased opportunities for knowledge and thought, for comfort and leisure. The amateur had his pleasure and his benefit in keeping in motion the current streams of thought.

As "cultural" advantages spread to the masses of the people, however, an adjustment had to be made to a new scheme of values. An appreciation of music and painting and singing, as represented by the professional artist, became a desirable mark of distinction as well as a thing to be developed for its own sake, and accordingly imitation of the arts was considered correct. The Victorian generations that were taught to play the piano and sing songs for assembled guests, to paint in water color with proud determination, represent a kind of amateurism which is an adaptation to a new social order. New found money, leisure and opportunities gave to the common man a wider acquaintance with the arts than he had ever had before. He was not always able to appreciate his opportunities as he felt he should, but he realized their value as an indication of position and knowledge, as an index of the gentility he considered desirable. This was amateurism which resulted from fashion and a desire for at least the outward and impressive qualities of aristocracy, but it did more than lectures could to lay the basis among the people for an understanding of the arts.

As the masses of the people have reached financial ease and social security, their amateur activities have again changed in emphasis. Professional delineation, which is necessary to the recognition of amateurism, has become so sharply accentuated that it tends to be esteemed as an end in itself. An attitude is thus set up which is inimical to the amateur and ultimately impoverishing to the expert. When recreation is systematized and made commercial without the vigor of individual enterprise, the personal effort which is indispensable to amateurism is likely to be chilled. The radio and moving pictures, social intercourse based on objective amusement, have made the individual of the present generation very largely a recipient rather than a communicant. He is more inclined to pay for his recreation than to supply it through his own efforts. The desire for economic position represents a ceaseless striving which is not easily discarded at will. It carries over beyond the working day and makes real leisure a thing to be shunned or, if imposed, a thing to be got rid of.

At the present time, therefore, there are more amateurs among women than ever before. The relaxation of their conventional duties has given them time for broader interests, while men are becoming more restricted and more converted

to the dogma of energetic money making and easy recreation. Women's clubs' activities may be largely the result of boredom, of superficial curiosity, of social competition, but they represent a kind of amateurism which is typical of the period that produces it and which has a considerable formative influence. They are an example of the tendency toward organization even in presumably individual activities. The little theater in fact is an amateur movement so well organized that it is often practically professional. Sports have clearly marked professional boundaries, but the division is entirely arbitrary. It is based on commercial considerations and also on the lingering feeling that sports are the province of the gentleman. The amateur status is therefore jealously preserved, but it is often similar to the position of the nobleman poet who is an amateur merely by convention. The influence of contemporary ideals of organization has extended even to the individual layman who enjoys his sketch block and water colors, his basement carpentry bench, his piano, for the very commercialism that makes him so formally an amateur contributes all its ingenuity to his convenience. Amateurs have never been so unanimously classified, but neither have they ever been so well served. Their work is given little consideration in a professionally paced society, but their whims are recognized as a profitable indulgence.

It is not for the quality of his work, however, that the amateur is significant. His activities are designed for his own pleasure, and as a means of expression for interests and talents which circumstances have made subsidiary they are of as much value as any other kind of educative recreation. To millions of persons they give that consciousness of creation which is a desire perhaps even more prevalent than the desire to enjoy and which, though it may be an illusion, is as necessary a one as that of achievement. Moreover the amateur, in following his interests, trains himself inevitably for a better appreciation of the kind of work he does, and is therefore an important influence in maintaining professional standards. An amateur painter is better equipped to understand the work of the trained artist because he realizes more intimately the problems that must be met. In this way also he serves, perhaps unwittingly, the function of a medium. By his appreciation and emulation of the achievements of others he is able to give them the homely qualities of recognition which make them intelligible. The

artist paints his picture and leaves it to the world, but if the public that receives it knows nothing of the process of its creation, response finds form in catchword criticism and superficial and irrelevant analysis, in pretentious praise or smug damnation. Also, by the very nature of his purpose, the amateur is little bound by the restrictions of tradition and competition and is therefore free to innovate what the professional often recognizes ultimately as desirable. The ideals of the little theater, for example, were made commercially safe by amateurs. It is not entirely true that an uncreative age produces few artists. Rather should it be said that an uncreative age cannot nurture its artists. Not even a specialist can work in isolation. He needs an interpreter and it is this that the amateur becomes.

AMBROSE (c. 340-97), church father. He was born in Trèves, the son of a Roman officer of high rank. He was educated at Rome in the humanistic tradition of the age of Constantine, and entered first upon the career of a high Roman official. In 370 he became consular prefect of northern Italy, with headquarters in Milan. When urged by the people he accepted the office of bishop, although he had not been ordained or even baptized. He held it until his death, achieving such distinction that Milan, like Rome and Carthage, became an important center in the formation of Latin Christianity.

Ambrose was unlike Augustine in that his lasting influence was due to his personality rather than to his writings. The nobility of his character, which had captivated the populace, was largely instrumental in converting Augustine to the church. His native capacity to rule enabled him, as a representative of the church, to reject successfully the claims of the empire for the first time in history and, with no other weapon at his disposal than the strength of his faith, to subordinate the acts of the Christian

emperor to the moral dictates of the Gospels. As scion and conqueror of the Roman nobility Ambrose assumed leadership of the Milan church and became the venerable prototype of church princes throughout Catholic history.

Ambrose originated *Latin church singing* and composed some of the most beautiful of the Catholic hymns. The quality of his writing became less distinguished, however, as its character became more impersonal. Accordingly a descending line can be traced from his poetry through his letters, orations and sermons to the larger theological-scientific treatises.

The importance of Ambrose as a scholar and theologian rests chiefly on his work in Christianizing and Latinizing the pagan heritage in education and theology. He made excerpts from Philo and Origen; he made available to Roman Catholicism the works of the Greek church fathers and of the Alexandrian philosophers; and he adapted to the uses of Christianity Cicero's work, *De officiis*. In his own *De officiis ministrorum*, with its carrying over of the stoic doctrine of duty, he produced the model for all homiletic ethics and at the same time furnished authoritative support for such specific doctrines as that private property is not in accord with natural law. His letters and orations have been frequently cited to prove that, while palaces may be subordinate to the emperor, churches are subordinate to the bishop (*Epistola 20* in Migne, vol. xvi, col. 999), or that in matters of faith emperors are not the judges of bishops but bishops the judges of Christian emperors (*Epistola 21* in Migne, vol. xvi, col. 1004).

AMENDMENTS, CONSTITUTIONAL. An adequate provision for amendment is implicit in the very nature of a constitution. Not only must it be possible to adapt the fundamental law to changing conditions, but any government

founded on the democratic principle of popular sovereignty must make possible the fresh assertion of the popular will as that will changes. For these reasons most modern constitutions either contain specific machinery for their own amendment or are recognized as changeable in some less formal manner.

The term "amendment" connotes a definite and formal process of constitutional change. Used in this narrower sense it describes but one of the methods by which constitutions are altered. This formal method is supplemented by the force of tradition and custom which may vitally alter the constitution, by judicial interpretation and by the enactment of statutes which affect the organic structure of the state. All of these processes of change are discernible in the evolution of the Constitution of the United States and of those of the several states.

Bryce classified constitutions as "flexible" and "rigid" according to whether they can or cannot be changed by the same process by which ordinary laws are made. There are, however, many degrees of flexibility and a wide variety of methods for effecting the revision or amendment of fundamental law. The British constitution, often loosely described as "unwritten" since custom and common law enter so largely into its make-up, may be modified by Parliament by the procedure used in passing an ordinary law. But there is a fairly well solidified tradition that constitutional changes shall be made only after a general election which affords opportunity for a popular mandate on the change. The written constitution of France may be amended by a joint assembly of the two houses of Parliament meeting at Versailles after they have separately declared in Paris in favor of the change. The constitution of Switzerland can be amended only by a majority vote of the people, which must also be a favorable vote in a majority of the cantons. Proposals for such amendments may come either from the federal congress or in the form of an initiative petition signed by 50,000 voters. The new German constitution may be amended by a two-thirds vote of both houses of parliament. If the upper house (Reichsrat) rejects a proposed amendment it becomes valid in two weeks unless the objecting chamber demands a popular referendum. Amendments may also be proposed by popular initiative and adopted at a referendum election. A proposal voted upon in referendum must be approved by a majority of the registered voters. In most of the new states of Europe constitu-

tions set up since the World War are easily amendable by legislative action alone.

The Constitution of the United States is of the rigid type, though less so than its predecessor, the Articles of Confederation, which could be amended only by a unanimous action of the states in Congress voting as units. Article 5 of the constitution sets forth the procedure for amendment. Amendments may be proposed in two ways: by a two-thirds vote of both houses of Congress (i. e. two thirds of a quorum); or by a convention called by Congress upon petition of two thirds of the states. No such convention has ever been called. Amendments may be ratified either by the legislatures of three fourths of the states or by conventions in three fourths of the states, as Congress may determine. Congress has always designated the former method.

Through July, 1926 (the last official compilation), nearly 2500 resolutions had been introduced into Congress proposing, it is estimated, over 3000 changes in the constitution. Of these Congress adopted and submitted to the states for ratification only twenty-four, nineteen of which have been ratified. Those failing of ratification are two amendments submitted in 1789 with the first ten, one of which related to apportionment in Congress and the other to the pay of members of Congress, one in 1810 forbidding acceptance of titles of nobility, one in 1861 prohibiting interference with slavery, and one in 1924 authorizing federal child labor legislation.

In view of these facts it was natural that the opinion should spread that the constitution was too difficult of amendment. Writing in 1885 (*Congressional Government*, Boston 1885, p. 242) Woodrow Wilson observed: "It would seem that no impulse short of the impulse of self-preservation, no force less than the force of revolution, can nowadays be expected to move the cumbersome machinery of formal amendment erected in Article Five." Proposals of easier methods of amendment were urged in the nineties by the scholars John W. Burgess and Munroe Smith (see Burgess's *Political Science and Comparative Constitutional Law*, 2 vols., Boston 1890-91, vol. i, p. 150-54, and Smith's "Shall We Make Our Constitutions Flexible?" in *North American Review*, vol. cxciv, 1911, p. 657-73). Their suggestions included proposals of amendments by bare majorities in two successive congresses and reduction in the majority of states necessary to ratification. Proposals in Congress for an easier

amendment process became both frequent and varied. These usually included a method of proposing amendments by petition of a certain number of state legislatures or by a petition signed by a certain percentage of voters in a definite number of states, and a form of ratification by popular vote either in the states or the nation at large. The details of the proposals may be studied in H. V. Ames' monographs.

An interesting change of attitude with regard to the amending process has been discernible since the adoption of the Prohibition Amendment in 1919 and the Woman Suffrage Amendment in 1920. These were ratified in the legislatures of certain states in which the proposals would have been defeated in popular referenda. Thus many who had regarded the referendum as a dangerously radical device now advocated it as a conservative check which ought to be included in the process of ratification of amendments, and numerous proposals to that end have been made in Congress. These proposals have frequently specified also that where ratification is to be by state legislatures, such action may not be taken until after a legislative election in which the people may give their representatives a mandate on the proposed amendment.

Amendments to the forty-eight state constitutions are made by highly diversified methods. Every state constitution sets up some procedure for its own change or revision. These methods are of three general types. The first is by constitutional convention which is used for more or less thoroughgoing revision. Such conventions may be called in every state except Rhode Island. In the second place every state constitution, except that of New Hampshire, may be amended by the process of legislative proposal and popular ratification. This is the method followed for making isolated changes in the constitution or additions to it. In more than a dozen states (thirteen in 1928) a third procedure obtains whereby amendments may be proposed by popular initiative by means of a petition signed by a definite percentage of the qualified voters. These proposals must be ratified in the usual way. The varied details of these methods may be studied in W. F. Dodd's book on the subject, and more briefly in the recent treatises on state government.

The question of how difficult or easy of amendment a constitution should be is not a simple one. The answer to it should depend largely upon what the constitution contains.

If its provisions, like those of the federal constitution, are all of fundamental import, then a method of amendment or revision is desirable which is sufficiently deliberate and restrictive to assure the most careful and mature consideration of the fundamental law. Our state constitutions, however, all contain many provisions of temporary or relatively trivial import, placed there frequently as a result of popular distrust of our state legislatures. It seems clear that constitutions containing clauses of this character should be easier to amend than those which contain only fundamental law. Otherwise these transitory and detailed provisions cannot be kept adequately adjusted to the changing demands of public policy. It has been suggested that parts of the same constitution might be amended by different methods. Thus a fairly difficult method might be made applicable to the fundamental parts of the constitution, while an easier procedure could be used to change those provisions of the constitution which are essentially legislative in character. Oklahoma and Virginia have applied this principle in a minor way by setting up a fairly rigid method of amendment for general use but providing that certain detailed sections might be altered by the legislature alone after the lapse of a certain length of time. The problem of the degree of flexibility of constitutions may ultimately be solved along these lines.

AMERICAN FEDERATION OF LABOR is the experimental outcome of labor movements in America, Germany, Great Britain and France. Here in North America the two nations of Canada and the United States, the continental variety of economic conditions, the mixed sovereignty of forty-eight states and one federal government, the domination of local politicians combined in two national parties, the successive waves of immigration from all lands and a remarkable mobility of labor, have afforded the scope and imposed the necessity of bringing together in one federation over an entire continent as many varieties of unionism as may be found in other lands more limited and uniform in their circumstances. The leading originators of the federation, in 1886, had previously, in 1881, taken over, almost verbatim, the constitution of the British Trades Union Congress, and that imported form of organization is perpetuated in forty-eight state federations of labor. Other originators of the federation had participated in or struggled against three preceding strictly American organizations—the National Labor Union, the Greenback Labor party and the Knights of Labor—each of them a product of the deflation of prices after the Civil War. The federation had to adapt itself to the individualistic psychology of these American movements unknown to other countries. Still other originators had participated in the American trade unions which began or expanded in the Civil War under American, British, Scotch and latterly Irish leaders.

The anarchistic exiles from the Paris Commune of 1871 and the communistic exiles from Germany's attempted suppression of socialism furnished, during the miserable decade of the seventies, leaders of desperate strikes, of street demonstrations, and finally the "Ten Philosophers" from whose eager deliberations the American Federation of Labor derived its first organization in the cigar shops of New York, 1879.

From the National Labor Union (1866-72) and the Greenback Labor party (1874-80) the men who later organized the American Federation of Labor learned a painful lesson: the futility of a labor party which had necessarily to be founded on alliances with frantic farmers and small business men against their organized opponents, the bankers and big business men under the guidance of expert managers of American machine politics. Such alliances could last

only while the slump in business continued.

From the Knights of Labor (1869-86) they learned that miscellaneous organized labor was incompetent to manage productive cooperation with the purpose of displacing capitalism by a voluntary cooperative commonwealth; and they learned that this same miscellaneous labor, while it might win sudden mass strikes, could not keep the winnings.

From the French exiles they learned that street demonstrations brought to the front the facile intellectual agitator against whom the workers in the shops were helpless and by whom they were misled; the American leaders could not even share the French anarchists' glorification of street barricades.

From the German communists and the teachings of Marx they learned that their immediate opponents were the employers who owned the shops, and that their enduring alliances must therefore be not with farmers and small business men, since these included their own employers, but with other wage earners in the shops of competing employers. But they had also learned from the National Labor Union and the Greenback Labor party that a labor party in America must include these same farmers and business men against whom, as employers, they must proceed, as communists, by confiscating their shops and usurping their management.

From the British and American unionists and from the Knights of Labor they learned that labor could not be lifted as a mass, nor business and banking defeated as a mass, and that sporadic organizations in single shops could not accomplish improvement; that their immediate opponents were the competing employers in the same line of business, and their organizations of labor must be separated along competitive lines so as to extend to these competing employers and no further. They learned, too, from the British unionists, but not the American, that they must build for permanent organization which could withstand the cycles of business depression and unemployment.

This learning by experience was the outcome of the deliberations of the "Ten Philosophers," about whom Gompers writes in his autobiography. Gompers, the Jewish cigar maker from London, and Strasser, the German cigar maker, proceeded to organize on the British model first the New York and then the national cigar makers and later the whole labor movement. This last organization was known as the Federa-

tion of Organized Trades and Labor Unions of the United States and Canada.

It was found after five years' experiment with this British model (1881-86) that it really concealed two different functions—legislation and organization—which had to be separated, intensified and subdivided in order to fit the variety of American conditions. Out of the reorganization based on these discoveries came the American Federation of Labor, in 1886. Legislation had to be split into federal, state, municipal, Canadian and provincial. So the new organization, for legislative purposes, split the Trades Union Congress eventually into forty-eight state congresses and the Canadian Trades and Labor Congress with federations for the provinces of Canada, in order to fit the political divisions of the whole North American continent, and changed "United States and Canada" in its name to "American." Several of the trade unions similarly prefixed the word "international" to their names, meaning thereby "North American." While the British organization had its one parliamentary committee and its annual congress of all the unions, which eventually became, by alliance with the socialists, the British Labor party, the American federation has its executive committee and congressional lobbyists at Washington, affiliated with an independent congress at Ottawa for the Dominion of Canada, but supreme over the federations of the states and Porto Rico.

Like the British organization, and also like the Knights of Labor, the federation has its city central federations, which in Russia became the Soviets. These local federations in America are also linked up with municipal politics, and have even conducted independent municipal campaigns, the most notable being the unsuccessful Henry George campaign of 1886 in New York, conducted by the Central Labor Union in alliance with socialists and single taxers, and the successful McCarthy campaign of 1909 in San Francisco.

The second function, separated from the other functions and immensely emphasized in America, is organization of the unorganized into local unions, their allocation to membership in the several national and international unions, and mutual support among all the unions in offense and defense on the economic field. The American Federation of Labor has as high as a thousand diminutive "federal labor unions" directly under control of headquarters at Washington. These are always in process of

formation and dissolution as recruiting stations for existing or new national unions. The federation supports from its own funds from twenty to fifty general organizers in various localities, who give their assistance to incipient unions and older unions. It appoints special organizers for concerted action or sympathetic strikes, as in the case of the steel strike of 300,000 workers in 1919, or in the organization of the 35,000 Italian subway workers in 1902 in New York. The strikes themselves are conducted by the affiliated unions; but the federation officials and organizers lend their aid, and at times are a means of collecting large sums of money as their substitute of "moral and economic force" for the sympathetic strike.

The union label, an American invention first adopted in California to exclude Chinese workers from the shops and then copied wherever the consuming power of union labor could help, has been, for unions like brewery workers, cigar makers, employees on workmen's garments and others, an instrument of importance in the program of mutual support. The label is organized labor's trade mark, protected against infringement by state and federal legislation, like the trade marks of capitalism.

Thus the economic problem of organization became the decisive point in the reorganization of 1886. The experience of five years with the British model showed that nothing could be done with the national political parties. The letters of the federation were unanswered and its agents unheard. Besides, at that time Congress had not undertaken labor legislation, the federal courts had not begun to use the injunction against labor unions or to declare unconstitutional the labor laws of the states. There were very few such laws anyhow, and they were state laws, since the states were then deemed to be sovereign in such matters. Hence the reorganization of 1886 provided for state federations whose main purpose should be legislation, while the national federation specialized on the expansion of economic organization in all the states. Its headquarters were established in Indianapolis, a thousand miles from Washington but a convenient railroad center for reaching all parts of the country. Not until 1896, after federal injunctions and judicial unconstitutionality had nationalized labor legislation, were headquarters moved to Washington, where the executive committee could reach the Congress, the president and the departments. Federal labor legis-

lation eventually became equal and even superior in importance to widespread organization, for the federal injunction challenged the right of unions to exist except on paper, and unconstitutionality challenged the usefulness of state federations of labor.

But in 1886 the problem of organization was supreme. The contest with the Knights was approaching its climax. The legislative constitution of the preceding five years was not fitted to this task. It provided only for a legislative committee without executive power between sessions. Nor were the trade unions of the country interested in national legislation—they were interested in defending themselves against the Knights, who in that year had reached the height of their power. Hence at a national conference of the officials of twenty-five unions and the legislative committee of the Organized Trades and Labor Unions, the latter disbanded and the national unions formed the American Federation of Labor. Samuel Gompers, secretary of the former legislative committee, was made president, and was reelected to this position every year, except one, until his death in 1924.

The federation proceeded, in 1887, to strengthen the voting power of the national unions. Delegates from national and international unions were given one vote for each one hundred members, leaving the delegates from city and state federations with only one vote. Thus in the convention of 1924 the eight carpenters' delegates cast 3152 votes and the one delegate from the central union of New York City cast one vote.

This method of voting, it will be seen, makes the American Federation of Labor not a popular representative assembly for legislative or political purposes, like the former British or German or French conferences, or like the former General Assembly of the Knights of Labor, or the former National Labor Union, but makes it a congress of ambassadors from sovereign unions, "weighted" according to the size of the union. The delegates from the unions are usually the national presidents and executive officers of the unions.

Thus no individual workingman is a "member" of the American Federation of Labor. He is a member only of his union, and it is his national union that is the member of the federation. There is even no dual citizenship, as there has been since the Civil War under the political constitution of the United States,

where every citizen owes allegiance both to the federal union and to the state of his residence. Each workingman is a "citizen" only of his own union, and gets representation in the federation only through the executive officers of his national union. Consequently the federation has no jurisdiction over individuals (except in the small federal labor unions above mentioned). Furthermore, since the federation has no funds of its own except the meager fund of one cent per member per month which the national unions each contribute in a lump sum, the federation remains with only "moral" jurisdiction over its constituent unions. It is a loose confederacy—not a federal union.

The result is that no "left wing" or "anti-administration" movement within any national union can get representation, or even a vote, in the federation convention, except as it comes from a city or state federation where the voting is legislative, democratic and equal for each local union, no matter how weak or strong it may be. As a matter of fact nearly all of the socialistic or communistic resolutions offered in the conventions of the American Federation of Labor have come from these local delegates, occasionally from a socialistic or politically minded national union, and then, after speeches, they are voted down ninety-nine to one. They have freedom of speech but no weight.

No wonder that the dissatisfied and sometimes revolutionary elements in this country and in others criticize the federation bitterly as "a machine," "boss ridden," "reactionary," even "a corrupt conspiracy of tyrants." The federation was organized and has been maintained expressly for organization purposes and to keep out disunion. Like the American political parties it is a "machine"—indeed its principle of organization has been named "business unionism" by Hoxie, a discriminating student of labor movements. In the American conflict of races and religions and of geographical sections, in a system of machine politics and highly efficient mechanized capitalism, and in the absence of any "class consciousness" or "solidarity" of labor, which in other countries is the heritage of centuries of military suppression, the American federation has just one "pure and simple" business—how to create a united front which is able to deal as one man with any situation regarding higher wages, shorter hours, slower speed, stricter shop control of jobs and permanence of unionism. The federation was created not as a political movement to over-

throw capitalism or get control of government, but as a movement within the ranks of labor to bring about permanent organization over a continent where everything conspired against both organization and permanence.

Hence when it came to dealing in 1895 with the Socialist Trade and Labor Alliance, or in 1905 with the syndicalistic Industrial Workers of the World, or in 1923 with the Communists, whose movements threatened to disrupt some of the unions, the federation was in a position to take drastic united action, expelling and suppressing them. The federation is truly a militant organization, but in a country where there is no class consciousness that unites labor regardless of organization, its militancy runs sidewise against disruptive labor movements even more uncompromisingly than frontwise against employing capitalists.

This lateral and frontal militancy within a disruptive environment affords an explanation of several peculiarities either wholly absent or unobtrusive in other countries and at former times in America. These are the small proportions of organized to unorganized labor, the wide spread of wages between high paid and low paid labor, dual unions, jurisdictional strikes, trade agreements and strict shop rules.

American industrial labor is much less extensively organized than the labor of other countries. While Germany, in 1924, was about 75 percent organized, England 65 percent, and Australia 60 percent, American labor was only 15 percent organized, including the relatively small numbers outside the federation. The percentages were larger in all of these countries at the peak in 1920. It may be estimated that in a city like Philadelphia a larger percentage was organized in 1835, when the ten-hour day strikes were first successful, than at any subsequent time. But those organizations lasted less than a year. In contrast with this and other similar disruptions, Gompers was able to report in 1897 that the unions of the federation had been able—for the first time in America—to maintain their organizations during a period of business depression. While only 15 percent of "organizable" labor is organized, this is an average of figures ranging from 100 percent organization in a few trades down to zero organization in the bulk of the industries.

Paralleling this diversity of organization is the diversity of wages and hours. Skilled labor in some of the organizations gets as high as \$1.75

per hour, six or seven times as much as the pay obtained by the lowest unskilled and unorganized in others, which falls to twenty cents an hour or less. Contrasted with this, formerly in America and now in other countries, the highest skilled labor obtained no more than twice or thrice the wage that went to the lowest unskilled labor. Hours of labor, too, run from thirty-five per week to seventy-five per week, while in other countries, as formerly in America, they are much more nearly uniform. Thus the diversity of American political and economic conditions is paralleled by the diversity of organization, of wages and of hours. The spread is more extreme than the difference between the building trades of London and the textile mills of Bombay. The former, transported to New York, are highly organized with high wages and short hours; the latter, to North Carolina, seem unorganizable with low wages and long hours. In some industries "industrial" unions, including the unskilled, have reduced the differentials formerly resulting from "craft" unionism.

These differential high wages are obtained largely by relentless prohibition of dual unions. The form of organization of the federation is designed for this purpose. If it is a congress of ambassadors rather than a house of representatives, then it follows that no territorial or occupational infringement will be permitted over the boundaries of each autonomous organization. England has 1100 independent unions, largely sectional rather than national—the American Federation of Labor has only 106 national unions, each dominating its local and sectional branches. Organized unions in Germany seem indifferent as to whose members get the jobs. It is enough that they are "organized," but not important to which union they belong. Perhaps this indifference is owing to class consciousness, equal wages and immobility. The American federation, instead of permitting different organizations to do the same work, is based on the principle of only one union for one kind of work throughout North America. This was its foundation from the start in 1881 and is even more solidly its foundation today. It means a federation of sovereign trade unions determined on mutual protection from dual unionism. Differential high wages, scarcity of high wage jobs, prohibition of dual unions and the absence of class consciousness, make the American federation a league of independent allies, not one big union.

But this independence has its weakness—jurisdictional disputes and jurisdictional strikes. The carpenters have conducted twenty contests with other unions on matters of jurisdiction. They have defied the federation, have been expelled from the Building Trades Department, have withdrawn, have conquered, have been taken back. Nearly all unions have had similar contests, but none so many. Jurisdiction means the power to make rules governing individuals respecting the materials, or tools, or kinds of work. The federation, when admitting a union, carefully and minutely describes its jurisdiction. If the claim of the union covers the total jurisdiction of a member union, it is a dual union and is excluded. But if it claims only a part jurisdiction, the highly technical problem must be agreed upon as to the lines of demarcation. This must be done over and over again, when new materials, new tools, new kinds of work, are introduced. But, even so, no method has been discovered by which jurisdictional disputes can be handled in such a way as to avoid jurisdictional strikes. Such strikes, especially in the building trades, have at times cost large losses in wages, in profits and in public sympathy. They damage friendly employers, but non-union employers escape. Leaders of the federation for more than thirty years have looked with dismay upon these disputes as a serious menace. The federation has tried all remedies except the compulsion which its constitution prohibits by denying jurisdiction over individuals. Hence the strength of the federation, its use of "moral force," is its weakness.

To the jurisdictional dispute must be added jurisdictional jealousy. When twenty-four different national unions had to unite in conducting the national strike of 1919 against the United States Steel Corporation for the eight-hour day in place of the twelve-hour day, the question as to which unions should have the thousands of new recruits from the previously unorganized brought forth internal dissensions and indifference to further organization, against which the federation was powerless and the corporation victorious.

However, its greatest achievement, and the one of which the federation is proudest, is the trade agreement. Often misinterpreted and misapplied, the trade agreement is the outcome of a constitutional convention of capital and labor for the economic government of competing establishments in an entire industry. It is a

flat denial of the communistic and syndicalist doctrine of an irrepressible conflict between "capital" and "labor." Historically it has usually followed a severe conflict extending throughout an entire industry. The first national trade agreement, originating in this way, was made for the iron and steel industry, 1866. The next was in the stove foundry industry, 1891. The latter became the model toward which federation policy focussed after the notable agreement in bituminous coal mining, 1898. The trade agreement means what the name indicates, an agreement between competing employers and competing laborers, throughout the competitive area and through their representatives, to stop their conflict by laying down shop rules for the regulation of the labor contract in all individual transactions.

The trade agreement is also a denial of the antimonopoly policy that culminated in the federal antitrust act of 1890, after centuries of insistence in legislation and in common-law decisions of the courts. But the trade agreement means not only acquiescence in but also advocacy of comprehensive organizations of capital, provided they are confronted by similar organizations of labor.

The trade agreement is not an agreement to prevent competition but one to regulate competition through uniform shop rules. It reduces "free" competition by introducing "fair" competition, as far as conditions permit. The American federation is a confederacy of unions each attempting to set up its own shop rules in its own industry. If the union is powerful enough, like the printers on daily newspapers, its rules are made not by trade agreement but by labor dictatorship. If the union is weak or non-existent, the rules are made by capital dictatorship. Between these extremes the rules are of great variety. Their purpose is evidently not the political or class conscious purpose of improving the condition of labor as a mass, but the individualistic purpose of affording greater liberty, equality and security for individual members within the competitive area. They cover such items as hours, speed, transfers, promotions, seniority, "hiring and firing," piece-work, discrimination, "victimization" of leaders, and they provide in various ways for interpretation, decision and appeal on individual disputes.

Shop rules, it is plain, are restrictions upon the common-law rights of the employer to manage his own business as he sees fit. Their

first tendency is to restrict output. But the fact that the trade agreement policy of the federation for forty years had looked to collaboration with employers, in place of conflict, led to the formal declaration of the convention in 1925, already put into practise by several unions, favorable to cooperation with management in eliminating waste and increasing efficiency for the mutual benefit of employers and employed. Thus the trade agreement is the federation's assertion that there is a conflict of capital and labor, but it is not irrepressible; that the evils are not in the capitalist system but in free competition; that competition can be made "fair" by shop rules under joint jurisdiction of organized capital and labor; and that this joint jurisdiction leads to cooperation with management in increasing the efficiency of industry.

The federation has been from the start anti-political and antilegislative. The trade agreement is evidently economic legislation, not political legislation. In this respect the policy of the federation fits the political system. American political parties are not founded on "principles"—they are business organizations of local professional politicians offering such promises, often different in different parts of the country, as they think will capture the voters. This means that they always take over from an independent "third party" whatever platform promises they think will dissolve that party and win its votes, if it appears to hold the balance of power. In the hope of this result the federation has always opposed a labor party and has always presented its legislative demands to the two dominant parties and to individual candidates, with recommendations that union members should vote for friendly candidates regardless of parties. This method is patently the only thing to do for an organization of only 15 percent of the voters. Sometimes the method gets results where strikes fail. After the federated unions lost the eight-hour strike in the steel industry in 1919, the Republican party leaders were reported to have induced the Steel Corporation to grant the demand voluntarily, which the corporation did in order to relieve the party of the incubus created by its victory over 300,000 workers. Similar paradoxes have occurred in the federation's history. The fact that administrative officers of government are usually elected by popular vote, whereas in other countries they are appointed by a legislative committee in control of the government, makes it even more

important for the federation's executives to use their influence with the administration rather than the legislature. It is in the administration of laws—local, state and federal—that the organizations both of labor and of capital accomplish their aims of nullifying objectionable laws, enforcing favorable laws, or interpreting colorless laws. This process does not require a political party.

But the method is precarious. Consistently, therefore, the federation's policy is anti-legislative. The primary reasons advanced against such legislation as that dealing with social insurance, hours of labor, minimum wage and the like are rooted in fear of government interference with the liberties of wage earners, thus reducing them to a "status." The "self-help" of laborers organized in unions, by which is meant the establishment of shop rules, enlarges the liberties of the individual workers. Yet the federation's policy calls for legislation in cases where laborers, like children, are too weak to organize and, in less degree, where women are involved.

Its position on these points is peculiar and baffled by the judiciary. Under the American constitutional system the judiciary is a third independent branch of government, having even superior power over legislatures and executives in the interpretation of an elastic constitution entrusted solely to the judiciary. For more than thirty years the federation has worked for what proved ineffective legislation intended to curb the judiciary in the issue of injunctions, whether in labor disputes or in the nullification of state and federal statutes. The political parties have repeatedly promised relief. But federal courts, especially, continue to extend their reach and to clip off one by one the instruments of organized action. The state courts then perforce follow the federal courts. The goal of the trade agreement, which is usually reached only after the destructive consequences of several years of aggressive organization, is thus deferred, perhaps demolished.

Even more baffling than the judiciary are the new tactics of many capitalistic concerns. The largest concerns, most vulnerable to public opinion and least pressed by competition, refrain from seeking injunctions, and direct their energies toward planning far in advance their own systems of shop rules taken over from the union schedule and designed to accomplish for their employees as much as, or

even more than, organized labor can obtain. The astonishing growth, during the past ten years, of "scientific management," "personnel administration" and "welfare capitalism," under the administration of experienced and well trained professionals who already have their professional associations and periodicals, along with the policy of paying higher wages for the increasing proportion of unskilled labor brought in by technological progress than labor unionism has been able to obtain, and in addition the restriction of immigration which the federation has always advocated, deprive the unions of the federation of most of their appeals to the unorganized. These workers, numbering about 1,700,000 employees as contrasted with 4,000,000 members of the federation unions, have been denounced by the spokesmen of the federation for their "yellow unionism" and "company unionism." Nevertheless they clearly show the need for new policies on the part of the federation if union organization is to continue and enlarge. These new policies are already taking shape, and experiments are being made. The federation has the beginnings of a research bureau; individual unions have even employed professional technicians to deal with employers in connection with matters which affect the welfare of the industry and of the workers; training schools have been set up for union members and apprentices; the federation supports a Workers' Educational Bureau; high officers of the federation and its unions participate in meetings with the professional managerial experts of non-union establishments; publicity is widely given to comparative statements intended to show that the policy of collaboration with employers is bringing more economies, greater profits and higher wages than the corresponding employee-representation plans of employers. Just as the leaders of the federation forty years ago started to turn the energies of organization from politics and socialism toward shop rules intended to stabilize small scale competitive capitalism, so now they begin to turn their energies toward collaboration with the new large scale stabilized capitalism.

AMERICAN LAW INSTITUTE, an incorporated organization of judges, practising lawyers and law teachers, "to promote the clarification and simplification of the law and its better adaptation to social needs, to secure the better administration of justice, and to encourage and carry on scholarly and scientific legal work," had its inception in an undertaking of the Association of American Law Schools. That association had been considering a project for a "juristic center" which should "direct the attention of law schools toward the improvement of the law." A special committee had this project before it and determined that cooperation of courts, bar associations, law schools and learned societies was desirable. Accordingly, at the annual meeting in December, 1921, a committee was appointed to bring about such cooperation. The result was a meeting in May, 1922, which formed a "Committee on the Establishment of a Permanent Organization for the Improvement of the Law." That committee (of forty, judges, practising lawyers and law teachers, headed by Elihu Root) prepared an elaborate report, setting forth the defects in American substantive law, the need for restatement, the form which a restatement should take, a project for organization of an American Law Institute and for a restatement of the law under its auspices, and an estimate of the time and money required. The expense of the preliminary investigation leading up to this report was borne by the Carnegie Corporation, which subsequently gave \$1,075,000 to finance the institute for ten years. The formal organization of the institute was completed in 1923, comprising the foremost judges, practitioners and legal scholars in the country. George W. Wickersham was elected president. At a subsequent meeting William Draper Lewis, former dean of the University of Pennsylvania Law School, was made director.

The work planned by the American Law Institute gives it a position of public importance and of significance for the future of American law. Two main projects have been undertaken:

a restatement of the substantive law and a model code of criminal procedure. The restatement was begun by taking up four subjects: contracts, torts, conflict of laws and agency. Property and business associations were later added to this group. Each study is in charge of a reporter who has working with him a number of advisers, chiefly law teachers, and of assistants. Frequent conferences are held and the drafts as they progress are submitted to discussion and criticism at the annual meetings and by the council. Thus the views of judges and practitioners from all parts of the country are brought to bear on the drafts, which themselves represent the study and judgment of law teachers from all the more important law schools. In addition state bar associations through cooperating committees have begun to annotate the drafts for each jurisdiction, stating and discussing the pertinent local decisions and statutes, if any, or noting that there are none, and pointing out the relation of the restatement of the general law to local peculiarities.

The process of restatement is a method peculiarly in accord with the spirit of the common law. Restatement is not codification although it is hoped that the authority of the institute will result in some of the benefits of codification. It is not directly unification although it is probable that it will act as a force in this direction. In the restatements the aim is to formulate the existing common law at its best in the form of succinct propositions with a commentary setting forth divergent views, reasons for the choice of one rather than another, general considerations bearing on the text and illustrations of the application of the propositions to concrete cases. This aim may be contrasted with that of the project for the model code of criminal procedure, where the purpose is not merely to restate but to furnish a model for legislative improvement of the existing practise.

While the restatement proceeds entirely on the basis of the authoritative legal materials, making no attempt to refashion them with the aid of the social sciences and in the light of demands other than those of legal theory, it is a necessary forerunner of any effective refashioning. We must first master the authoritative legal materials which are to be reshaped. In doing this preliminary work thoroughly and in unifying the body of substantive law at a time when the economic situation of the country calls for a giving up of local legal provincialism, the

institute is doing a conspicuous service to American administration of justice.

AMERICAN LEGION is an organization of persons who served in the United States forces between April 5, 1917, and November 11, 1918, the period of American participation in the European War. Unlike other veterans' organizations the legion admits women to membership since yeomen in the navy and nurses in the army were permitted military rank. The membership in 1918 was approximately 750,000; it was probably not more than 850,000 at the high point in 1922, although at one time a membership of 2,000,000 was claimed.

Organization of the American veterans of the World War was proposed by Colonel Theodore Roosevelt, Jr., in February, 1917, at a dinner of staff officers in Paris. Later (March 15-17, 1919) a caucus of one thousand representatives of various units of the Expeditionary Force was held in Paris from which was selected a committee of organization. A convention was called at St. Louis (May 8, 1919). The name "American Legion" was selected, and a constitution was adopted.

It was provided that the organization must not be allied to any political party; that the national commander should be elected at each annual convention for a period of one year and should not be eligible to reelection, and that no salaried elective officer should hold office in the legion. A tentative program for assistance to returned soldiers (government grants of land, rehabilitation of disabled veterans, improved administration of government insurance for veterans) was worked out. Posts ranging from fifty members upwards were chartered throughout the country, which was divided into departments usually following state boundaries; and the national headquarters was established at Indianapolis.

The object of the organization was stated to be "to uphold and defend the Constitution of the United States of America; to maintain law and order; to foster and perpetuate 100 percent Americanism; to preserve the memories and incidents of our association in the Great War; . . . to combat the autocracy of both the classes and the masses; to make right the master of might. . . ." Antiradical trends were further emphasized by the adoption of resolutions attacking the pardon or honorable discharge by the War Department of conscientious objectors, and condemning the Industrial Workers of the World, anarchists and international socialists. Peculiar conditions prevailed at the time of the organizing convention. A large section of public opinion greatly feared the extension of communist and radical activities in the United States. A political group desired to put forward Major General Leonard Wood as candidate for president in 1920. The problem of employment of returned soldiers was beginning to be acute.

With the tacit consent of the national organization many individual posts at once emphasized the radical issue and, officially or unofficially, took active part against the liberal side. Several hundred incidents are on record in which, following the policy of 100 percent Americanism, legionnaires were active in breaking up radical or socialist meetings, stopping concerts of German music, etc. In this and in the violence of expression often found in official legion publications and reports the legion merely reflected the wave of intolerance which was then passing over the country.

The most disastrous clash occurred between the legion and the Industrial Workers of the World at Centralia, Washington, on November 11, 1919. During the Armistice Day parade shots fired from a building occupied by the Industrial Workers of the World killed several legionnaires. The legion maintained that this was an unprovoked attack. The I. W. W. insisted that the legion parade had paused in its march to attack the I. W. W. headquarters, and that the shots were fired in self-defense. At the resulting trial of a number of members of the Industrial Workers of the World for murder, some were acquitted; others were convicted and sentenced to prison for murder in the second degree. The case remains an issue to date (July 1, 1930), there being considerable evidence to support the contention that the legion in Washington had taken sides in the struggle then existing between the I. W. W. and the lumber

interests with a view to eliminating the I. W. W. from Centralia, as well as to support the self-defense theory. Conflict resulting between the legion and labor organizations led to conferences (1922) between the commander of the legion, Franklin D'Olier, and Samuel Gompers, president of the American Federation of Labor, which brought about the establishment of an understanding between the legion and the right wing forces in the American labor movement.

The legion has often taken active part in projecting legislation, and has often been the beneficiary of minor legislative appropriations either directly by grant or indirectly by having extended to it the free use of government buildings or services. The great legislative issue of the legion has been the soldiers' bonus, or "adjusted compensation," the theory being that the returned soldiers should receive government grants equalizing their pay with that of laborers in civil life during the war. The question divided the country. A national campaign was instituted by the legion calling for grants by way of cash and paid up insurance, but it was opposed, especially in the East, by a large section of the public headed by Andrew Mellon, secretary of the treasury. Some sentiment in the legion likewise opposed it, e.g. the Willard Straight Post (New York); but the national organization was decisively for the measure. Proposals for a bonus in cash proved unacceptable, and a bill requiring grants by way of paid up insurance was introduced and passed in 1922 but vetoed by President Harding. In 1923 the bill was reintroduced with amendments. It was vetoed by President Coolidge but passed over his veto in 1924. At the same time the legion both nationally and in the various states conducted campaigns of varying success to give veterans preference in all civil service appointments and to place under legion supervision the operations of the Veterans' Bureau in Washington. A campaign for universal military training, although endorsed by the national convention of the legion, found legion sentiment divided and proved abortive.

On the humanitarian side the legion's activities, although less spectacular, have been more fruitful. In 1919-21 an extensive campaign, especially in the East, for reemployment of returned soldiers proved fairly effective. Individual departments of posts provided hospitals for disabled and tubercular veterans, cared for dependent children of the legion, located missing soldiers and gave assistance to veterans who desired to obtain or collect insurance or to

secure other aid from the government. As the war receded, individual posts, through their club activities, have entered more generally into the life of their various communities, so that at present the legion forms one of the many national fraternal organizations whose individual units are a part of the social framework of many communities.

Politically the legion has to a considerable extent avoided the charge of creating an office seeking group. But the organization has nationally or locally supported or opposed individuals in public life. Men prominent in legion affairs have frequently entered political life, notably Theodore Roosevelt, Jr. (assistant secretary of the navy, candidate for governor of New York in the election of 1926, governor of Porto Rico) and Hanford MacNider (formerly national commander of the legion and subsequently assistant secretary of war); and the legion has continuously been a factor in local politics, especially west of the Mississippi River. A considerable number of posts supported the candidacy of General Wood for the Republican nomination for president in 1920. Legion sympathies were enlisted against the activity of the Non-Partisan League, the Farmer-Labor party and the La Follette candidacy in 1924. Although political activity was a factor in the 1928 election in Iowa and Nebraska, it has tended to diminish in recent years. In 1927 the legion received a great deal of public attention because of the trip of 20,000 legionnaires to Paris under semi-official government auspices. At present its national policies are largely concerned with the administration of the Veterans' Bureau and of the War Department, although it has also objected to diminishing the navy program. It continues to some extent its propaganda for Americanism and has never abandoned the welfare and relief work commenced in 1919.

AMERICAN PROTECTIVE ASSOCIATION. See PARTIES, POLITICAL, section on *United States*.

AMERICANIZATION involves the social adjustment of the immigrant to the American environment—the processes of social assimilation by which immigrants in the United States come to participate in the common life of the nation and to identify themselves with it in thought and feeling. It is a slow and organic process which cannot be isolated from the totality of the immigrant's experiences and relationships in the United States. Fundamentally the problem of Americanization is the problem involved in any migration from one social group to another, the bringing together of the traditions of the immigrant's old and of his new community.

As it is commonly used at present Americanization suggests something other than the play of natural social forces. While the word has been employed for years, it was not until the World War that it gained wide currency. It was then that the heterogeneous character of our American population first became a matter of serious national concern. Prior to that time it had been generally assumed, except for anti-foreign outbursts among certain groups in the 1850's and again in the 1880's, that the American environment would of itself exert those pressures upon the immigrant which would make him an integral part of the American community. But when the war revealed many groups of immigrants voicing the national aspirations of their kin in Europe, war time efforts to arouse American national sentiments and weld national interests resulted in a formal movement of "Americanization" designed to supplement the play of natural social forces.

In most quarters this Americanization movement concentrated on teaching English to the immigrant and stimulating his naturalization. In many states the teaching of common school subjects in any language other than English was prohibited by law. This emphasis on the learn-

ing of English and on naturalization, together with the unfortunate atmosphere of coercion and condescension in which so many war time Americanization efforts were conceived, had the effect of bringing the word into a disrepute from which it has never fully recovered. Contributing to the same result, in the period following the war, were the widely expressed fear and suspicion of the immigrant, his frequent indictment as a radical, attempts to suppress his newspapers and organizations, the ignoring of his own culture and aspirations, the charge that certain nationalities and races were inferior and unas-similable, and the use of intimidating slogans. Americanization work too frequently made the assumption that American culture was something already complete which the newcomer must adopt in its entirety. Such attitudes and activities were important factors in promoting restriction of immigration, but they did not advance the assimilation of the immigrants who were already in America.

The principal agencies now doing Americanization work, in the more limited meaning of the word, include our public schools, religious and patriotic societies and a large number of independent and miscellaneous organizations, supported for the most part by voluntary contributions. Industries employing foreign born workers, chambers of commerce and women's clubs have frequently undertaken or sponsored Americanization work.

Evening schools for adult immigrants, maintained by most cities, are the chief governmental Americanization activity. For the most part instruction is limited to English and the elements of American history and civics required of candidates for naturalization. While many state governments make it compulsory for local boards of education to organize such classes, only a few share in their expense and the main burden of immigrant education rests on local communities. As a rule the state departments of education organize teacher training classes, develop methods of instruction and stimulate or supervise the activities of local school boards. In some cities, in addition to the evening schools, foreign born mothers are reached through home teachers and neighborhood classes.

Various states, conspicuously California and Massachusetts, have in addition to educational activities created special departments to protect the immigrant, investigate and adjust his complaints, promote better housing and inspect

labor camps. Among other government Americanization activities should be mentioned the work of the public libraries, many of which provide special facilities for immigrant readers. The United States Bureau of Naturalization formerly did extensive citizenship training work but at present this organization limits its activities to administering the naturalization law.

Equally important and extensive is the Americanization work of private organizations throughout the country. In almost every large city there is at least one citizens' bureau, Americanization committee or similar organization, designed to encourage naturalization, prepare the candidate for citizenship and assist the immigrant in adjusting some naturalization or other difficulty. Many large religious organizations, Protestant, Catholic and Jewish, maintain special immigration or Americanization divisions which meet or assist the newly arrived immigrant, help him with his personal problems of adjustment and carry on extensive educational activities in his behalf. Similar aid is extended by the travelers' aid societies and other non-sectarian agencies. Social settlements, the international institutes maintained by the Y. W. C. A., and many community centers, churches and welfare organizations are not only doing social service work for the foreign born but are also trying to establish friendly relations between individual immigrants and the native born.

Another important type of work is that which is being carried on among immigrant groups by their own organizations, national societies, parochial schools, educational institutes, mutual benefit and welfare associations. These organizations bind together national groups and seek to make their Americanization a process of amalgamation, not of substitution. Instead of treating the individual as a unit, assuming that he can be transformed, they work upon the group, thus relieving the strain which adaptation places upon the unsupported individual.

Important as these conscious efforts are toward Americanization, they represent only a part of the social forces which play continuously upon the immigrant and determine the degree and rapidity of his assimilation. A conspicuous force which makes for adjustment is the urge to achieve material success, which makes the immigrant adapt himself to American ways of work and business. This usually involves learn-

ing the English language as quickly as possible. Standardizing forces such as national advertising, ten-cent store products, movies, radio and the tabloid press play also upon the immigrant. An American neighborhood which receives the immigrant on a footing of social equality with the native born, American schools which give him an opportunity to educate his children, and industrial concerns which grant him good working conditions, a decent standard of living and a chance to advance act as agencies for Americanization. Assimilation is also facilitated by English or foreign language newspapers which furnish the immigrant much of his information about American laws and institutions, communities which provide for adequate housing, recreation and playgrounds, and political organizations which initiate him as a participant in American democracy.

These influences work with varying force upon individuals in small or large immigrant groups, agricultural or urban communities. Their effect is largely determined by the individual's own experience of prolonged unemployment, poverty, exploitation, separation from wife and family, inability to find redress for his grievances, isolation in overcrowded or squalid immigrant quarters, social discriminations, or by his acceptance into a community with adequate housing and recreation facilities and into an industry with good working conditions. Immigrant adaptation is further complicated by such problems as those arising from the transplanting of the land conscious peasant to a restless industrial community and by industrial dislocation in periods of unemployment or depression. However, an unsophisticated group whose chief fund of culture consists in a store of folk customs and folk wisdom necessarily enlarges its horizon chiefly in American terms rather than in those of its fellow countrymen. On the other hand those immigrants whose home experience is broader and whose own cultural background is richer have more to contribute to the making of American culture.

AMES, FISHER (1758-1808), American political writer and publicist. Ames was born in Dedham, Massachusetts; was graduated from Harvard College, a precocious and delicate youth, in 1774; read widely at home during the war; and was admitted to the bar in 1781. His newspaper essays during Shays' rebellion and speeches in the Massachusetts convention of 1788 gave him a reputation as publicist and orator. He served in the first four Congresses (1789-97) as a staunch Federalist, and his speech on Jay's Treaty was the greatest of that generation. In a series of essays in Boston newspapers between 1798 and 1808, he provided a philosophic basis for New England Federalism. In ancient history, from which most Americans read the lesson of tyranny, Fisher Ames found a warning against democracy. Starting with the premise that men are naturally evil and are influenced only by a desire for wealth or fame, he deduced that democracy must be a government of the worst and end in anarchy or despotism. Regarding England as a bulwark of religion and rational liberty, and Napoleon as the incarnation of the revolutionary spirit, he devoted much of his writing to the European war, and to denouncing the foreign policy of Jefferson and Madison. His classical allusions and crisp, nervous style gave his essays wide vogue among educated people, although they passed over the heads of the public; and among the ruling class of New England his position was analogous to that of Calhoun in the South of 1850. A collection of his essays was published posthumously in Boston in 1809 and partially reprinted in England in 1835 as a warning against democracy. His *Works*, edited by Seth Ames (2 vols., Boston 1854), contain a biographical sketch.

AMES, JAMES BARR (1846-1910), American law teacher and jurist. In 1873, shortly after his graduation from Harvard Law School, he was made assistant professor; in 1877 he became professor and in 1895 dean. His whole career was at Harvard. As a student he came under the influence of Christopher C. Langdell, recently appointed dean of the law school. The latter's ideas regarding methods of legal teaching were original and radical. Law was to be studied from first hand material in reported decisions of courts. The student was to employ the inductive process and to make his own syntheses. The opposition to Langdell, aroused by his radical theories, was not lessened when his disciple Ames, a young man without experience in the practise of the profession, was appointed to a professorship in the school. But the latter's genius as a teacher perfected the method which Langdell originated, and before Ames' death the case method, as it was called, was almost universally employed in the law schools of the United States. Through the preparation of a series of annotated case books and through his extraordinary power as a teacher he deeply influenced the legal thinking of a generation of practitioners, judges and law teachers. A few essays, particularly in the field of legal history, constitute very important contributions to juristic science. His "Disseisin of Chattels" and lectures on the history of assumpsit, in *Lectures on Legal History*, are legal classics.

Ames confined his researches rather strictly to the legal system of England and its development in the United States. He made little attempt to consider other systems, or to take account of social or economic elements, and almost entirely excluded legislation from his investigations. In short, he carefully marked off the province of law from that of other social sciences. Essentially his method consisted in the careful analysis of the reported cases, from the year books to the latest current report, with a view to discovering general concepts underlying the mass of judicial pronouncements. Although he studied case law as probably no other man of his generation, he was ready to reject precedent, to declare a result wrong, if it conflicted with principle.

In his later years an ethical tinge became more evident in his juristic thinking, especially in his treatment of equity, trusts and torts. Notwithstanding his devotion to the common law, he did not scorn the law of nature. It is

perhaps not so convincing today as it was in 1891 to describe as a "far-reaching principle of natural justice" the doctrine that "as between two persons having equal equities, one of whom must suffer, the legal title shall prevail" (*Lectures on Legal History*, p. 272). But Ames was able to make such a formula useful in producing harmony between apparently conflicting decisions in widely different parts of the law. His great service was the restatement of a large part of the common law in broader generalizations and clearer outlines.

AMMON, ALFRED OTTO (1842-1916), German anthropometrist and one of the founders of the anthropo-social school in sociology. His anthropometric measurements of recruits and students in Baden, Karlsruhe and Freiburg showed that city born people were more dolichocephalic than country born people; that migrants from the country to the city were more dolichocephalic than those who remained in the country; and that the upper classes were more dolichocephalic than the lower classes. Such facts were due, in Ammon's view, to the selection of the dolichocephals by the city and by the upper classes. On the basis of these findings he posited a correlation between dolichocephaly and migratoriness, and likewise between dolichocephaly and intellectual capacity.

Later on, by combining the Darwinian principles of heredity, selection, variation, struggle for existence and survival of the fittest, Ammon gave a systematic theory of the social order and evolution of society. The essentials of this theory are as follows: first, the basic characteristics of the social order and social evolution are determined by the above Darwinian factors; second, any society progresses as long as the proportion of the innately talented persons (dolichocephals) of its members does not decrease; third, the existence of social inequality and stratification is a natural result of the innate inequality of individuals; fourth, the upper classes are much richer in talented dolichocephals than the lower classes; fifth, the existing forms of social selection in western society are unfavorable for the survival of these upper

classes and they tend to decrease. At the present time many of Ammon's generalizations are known to be invalid.

AMNESTY, a concept of public law, comes from the Greek ἀμνηστία, which means forgetfulness or oblivion and implies an act of the legal sovereign conceding, from grace, a voluntary extinction from memory of certain crimes committed against the state. It is a legal oblivion, usually of political offenses. However, only the criminal consequences of the absolved act are destroyed. Civil recourse to reparation for damages to third parties still remains, unless the amnesty has been made by its terms to cover exemption from all legal recourse.

Amnesty is usually held to be juridically different from pardon in that it involves no nullification of a penalty already judicially determined in particular cases, but is a general determination that whole classes of offenses and offenders will not be prosecuted. Normally amnesty is carried into effect by statute rather than by executive order, unless a devolution of the power upon the executive has been granted, under a survival of executive prerogative such as exists in England and Italy and, perhaps one may say, in the United States. Joseph Barthélemy almost alone believes that amnesty, because it involves discretion, is an executive act and for that reason, under the French system, ought to be accorded by the parliament (not as a legislative power but as representative of the nation) but on the exclusive initiation of the government ("L'amnistie," p. 281-84). Others have held that it proceeds ultimately from the highest source of legislative authority, existing in the crown under constitutional monarchies, in the representative body under parliamentary republics. Owing to a refusal on the part of American courts to differentiate amnesty from pardon, the power is found both in presiden

and in Congress under the constitutional allocation of powers in the United States.

For purposes of formal classification amnesties may be said to be: first, general or particular, that is, they may cover all classes of political offenders or may be limited to special groups, with specific exceptions; and second, absolute or conditional, that is, they may impose no conditions or they may demand the performance of certain conditions before their provisions enter into legal effect.

Such a formal classification, however, oversimplifies the difficulties involved in an analysis of the concept. In Roman law it was extremely difficult to distinguish between amnesty and pardon. In continental law, with its Romanist traditions, the distinction between them is more finely drawn in theory than in practice. The amnesties granted often involve, in fact, commutation of sentences, as well as blanket indulgences.

American law, as well as English, possibly because of shared common law traditions, has been even less rigorous in the separation of amnesty from pardon. To be sure, American courts recognize a distinction between the two (*U. S. v. Bassett*, 13 Pac. 237, 239; 5 Utah 131; and *U. S. v. Wilson*, 7 Peters 160) and, although they take no notice of pardon unless it is pleaded, they apply amnesty as part of the law proceeding from the legislature (*State v. Blalock*, 61 N. C. 242, 247; *State ex rel. Anheuser-Busch Brewing Ass'n. et al v. Eby*, 71 S. W. 52, 61; 170 Mo. 497). Nevertheless some courts have held that "amnesty is included within the word 'pardon' which is generic, and includes every character of pardon" (*Davies v. McKeeby*, 5 Nev. 304-09; *U. S. v. Klein*, 13 Wall 128). The usual juristic distinction between amnesty and pardon is "not recognized in the law and, except that the term 'amnesty' is generally employed in pardons extending to whole classes and communities instead of to individuals, the distinction between 'pardon' and 'amnesty' is merely philological rather than legal" (*Knote v. U. S.*, 95 U. S. 149, 152-53; this case finally determined that amnesty was not a 'grant and did not entitle to recovery of property previously condemned and sold). It is on this reasoning that the courts have held that a general amnesty may proceed from an executive proclamation; this executive power, however, does not destroy the power of Congress to pass an act of general amnesty. Here is possibility for confusion, yet this deduction, in-

spite of congressional resistance to President Johnson, appears to be sustained both by the practice of the presidents and by the courts (see, for an extended discussion, 8 *American Law Register* n. s. 513-32, 577-89; and *Brown v. Walker*, 161 U. S. 591-638).

Some courts have further held that "the term properly belongs to international law . . . and has no technical meaning in the common law," on the ground, it would seem, that it often "is applied to rebellions which by their magnitude are brought within the rules of international law" (*Knote v. U. S.*, 10 Ct. of Cl. 397-407). It is hardly possible, in the light of political practice, to defend this contention merely on such a ground. Acts of amnesty have been applied to desertion and petty offenses. It is true, however, that amnesties of a general nature usually follow civil disturbances which have threatened the government, and that the granting of an amnesty is nearly always a sign that the government feels its position secure from violent overthrow, and that having disarmed its enemies in the field, it may proceed with the attempt at disarming hatred and resentment by an act of grace.

The first historical instance of an amnesty that shows a clear concept of its nature was the act by which Thrasybulus in 403 B.C., after the expulsion of the Thirty Tyrants from Athens, forbade the further persecution of citizens for their past political acts and exacted an oath of amnesty in an effort to erase civil strife from memory by the imposition of legal oblivion. In Roman law the *restitutio in integrum* was a rehabilitation amounting in practice to an amnesty. Every great civil struggle in which the victor has not pursued the defeated to complete extermination has of necessity been followed by an amnesty, tacit or legal.

French history, full of civil strife as it is, abounds in amnesties, first known as *lettres de rémission générale*. The *lettres d'abolition* in 1413 which accompanied the truce between the Armagnacs and the Burgundians were really an amnesty. Similarly in 1549 civil riots in Bordeaux were amnestied. The Edict of Nantes was partly an amnesty; and the whole nineteenth century was a long train of them, from Napoleon's imperial decree of 1802 to the successive amnesties up to 1881 following the civil disturbances of 1871 and the Paris Commune. Amnesties in favor of war time deserters, of communist agitators and of the Alsatian "Autonomists" have formed stormy subjects of debate since 1919.

In England the most famous amnesties include those after the Civil War in 1651 and that of Charles II in 1660. It is noteworthy that the latter excepted from the terms of the amnesty the judges who condemned Charles I to the block, though this was done by vote of a Parliament more vengeful than the king himself. The Fenians Act of 1873 and the amnesty to the Boers in 1903 are other typical amnesties.

The chief interest in amnesties granted by the federal government in the United States centers in the reconstruction period after the Civil War. Lincoln's Amnesty Proclamation of December 8, 1863, had been authorized by Act of Congress, July 17, 1862. It offered full pardon to those who took a prescribed oath, excepting certain classes of rebels. President Johnson's struggle with Congress grew in some measure out of his liberal Amnesty Proclamation of March 29, 1865, and from the congressional repeal on January 7, 1867, of the Act of 1862, by the authority of which Lincoln had proceeded. Johnson treated this repeal as a nullity and went about extending the provisions for amnesty in proclamations of September 7, 1867, July 4, 1868, and December 25, 1868, this last granting amnesty without the formality of oath. The question whether he was justified in subsuming amnesty under the executive's legal power of pardon has been disputed. Certainly he had precedents for his action in the presidential amnesty proclamations by Washington, Adams and Lincoln. (On the whole Johnson controversy see Edward MacPherson, *Political History of the United States of America during the Period of the Reconstruction*, Washington 1880, and *Political History of the United States of America during the Great Rebellion*, Washington 1876; also 12-17 *U. S. Statutes at Large*, appendices. For the legal effects of these acts see *Brown v. Walker*, 161 U. S. 591-638).

After the Great War the nationalistic settlements forced the incorporation of amnesty provisions in the armistice and the peace treaties. Amnesties became necessary also as a means of easing the bitterness which grew out of the post-war struggles of classes and minorities. Deserters of certain categories, those who had taken part in unsuccessful revolts and political offenders generally were amnestied. Because of the revolutionary and dictatorial character of their governments Italy and Russia furnish the most interesting illustrations since the war of strictly political amnesties.

In Italy the pre-Fascist governments were

notoriously lenient to deserters. When the Fascists came into power the tables were turned. Blanket extinction of Fascist offenses of violence (and of non-Fascist offenses where they did not arise from "purely personal motives") were brought under a royal decree of December 22, 1922, that included "crimes committed in agitation, strife, tumults or conflicts arising from economic-social causes" up to a certain degree of seriousness (*Racc. di leggi e decreti*, vol. vi, 1922, p. 5022). Later amnesties permitted the escape of certain enemies of the regime who were being detained, although the decrees were aimed primarily at absolving Fascists. Amnesty in Italy hardly affords protection from Black Shirt terrorism or from subsequent arrest by the political courts.

Not only post-war Russian experience but the experience under the czarist regime as well furnishes many instances of failure to execute amnesties in strict good faith. The fate of some of the mutineers of the Russian war vessel *Potemkin* will be recalled, particularly that of Matushenko who was condemned to death in 1907 despite the amnesty of October 21, 1905. The reckless disregard of their own promises by Denikin, Kolchak and other White Guard leaders after the revolution was quite in tradition. One need not be surprised, therefore, at the failure of the Soviet government to carry out with complete good faith the amnesty offered by the Presidium of the All Russian Central Executive Committee (decree of December 16, 1921, to all enlisted men of the White Guard military organizations, and a later partial amnesty to White Guard officers as well). The secret Cheka left no one in safety who had been or might be suspected as a counter-revolutionist.

It is clear, therefore, that amnesties are effective as legal protection only in constitutional states under the rule of law which courts can enforce, or in absolute monarchies or dictatorships where the ruler is of tried good faith. Wherever the government feels itself insecure they are of doubtful worth. In fact, from the standpoint of the group in power, amnesties are politically expedient only when the regime is safe from further violence, and when clemency may not be mistaken for weakness.

AMOS, SHELDON (1835-86), English jurist and law teacher. Amos carried on the Bentham-Austin tradition in jurisprudence. In common with that school he regarded law and legislation as synonymous, and continued to emphasize the idea that law is a command issued by the governing body to the governed. Austin's penchant for distinguishing law from morality is reiterated in Amos. Yet Amos outsteps his master by recognizing the existence of international law, to which Austin had denied the title of law "properly so called." But the concept of international law which Amos developed was made to fit in with the general theory of law as a command. To him international law consists only of such rules as have a positive sanction either in the local courts of the various states or by some other force, such as war. Between the periods of Austin and Amos, Sir Henry Maine had written his epochal treatises on ancient law; the influence of these works is discernible in the writings of Amos even while he verbally continues strictly to adhere to the Austinian doctrines. Without accepting Maine's view of law as evolving custom he recognizes the utility and validity of many of Maine's tenets and concludes: "History, descriptive sociology, Roman law, foreign law and international law, logic, ethics and politics, are none of them alien, are most of them essential, and are all of them helpful to the fit furnishing of the student of legal sciences."

AMUSEMENTS, PUBLIC. Literally, an amusement is something at which one gazes or stares; and public amusements are characteristically spectacles, but there are few forms of amusement which have not originally involved the active participation of every member of a group, whether as contestant in a game or as one of a chorus in a dramatic ritual. Most amusements have been group activities before they became mass spectacles. The commonly accepted distinction between amusement and recreation, which would limit the former to activities that divert without requiring any effort, is too narrowly drawn to the forms of an industrial civilization. The games and play to which modern man turns in a self-conscious attempt to regain strength and vigor, and which he calls recreation, have been among the important forms of amusement to people of other times. Even the most mechanized amusement retains something of the recreative value of the diverting; the recreative and the amusing are always intermingling. But amusements are primary; they are the spontaneous play patterns; in particular forms they may become cheap and repetitive and distorted, but they never lose the impress of activities which men have passionately enjoyed.

It is because one can best define amusements by reference to this emotional factor, to the attitudes which men have had toward certain occupations, that one must recognize as amusements a whole fringe of activities designed primarily for other ends. Thus one of the favorite amusements of the citizen of Athens was attendance at the speeches of the great orators; while the Roman found a similar pleasure in the debates of the Forum; and for the contemporary American the recurrent election campaigns are among the most popular of national sports. In the process of such transformation necessary activities are often elaborated that they may better serve as diversions. The pomp and splendor of the autocratic ruler, secular or priestly, ministers not only to his sense of greatness but furnishes all of the drama and pageantry that may come to large groups of his subjects. Even the execution of the criminal has been furnished out as the most entertaining of spectacles. And there is a pathology of cultural as well as of individual pleasure, which takes the form now of an Inquisition, now of a Cromwellian regime.

The actually existing variety of amusements

within any particular culture is determined by its economic resources, its social cohesiveness, its political structure, its relative isolation, its prevailing morality. But all the bewildering diversity of amusements which men of different civilizations and periods have known have been but variations of a few basic forms and patterns. Devotees of particular games and sports are fond of tracing their origins to remote and distant places—games of ball to Egypt, cock fighting to India or the court of the Great Khan, certain forms of athletic contest to Japan. But the relationship between modern amusements and those of Egypt is more fundamental than that of mere historical continuity; it is a functional similarity based on the shaping and reshaping of certain common elements into variant forms. Thus music and dance and the drama of religious ritual are universal; games and athletic contests find their place in modern recreational programs as they found a place in primitive life; exhibitions of strange beasts and men charmed the ancient Egyptian as they charm the modern circus goer or the courts of the native princes of India. There has never been a civilization without its individual mimics or clowns, its jugglers and performers of tricks. The strolling player and comedian wandered among the crowd at the Olympic games, initiated the literary drama in Rome, set up his stall in the fairs of mediaeval Europe as of old Japan, joined the great band of Elizabethan vagabonds, occasionally created a *commedia dell' arte* and finds shelter today in the circus or on the vaudeville stage. To the many whose daily occupations are more serious the masquerade has offered again and again a temporary escape from the bonds of personal consistency or of ordinary social standards. The element of masquerade was present in the earliest ritual dances; in the Roman Saturnalia or the mediaeval All Souls' Day it became the justification of a sudden wild escape into licentiousness; in pageant and carnival it heightened the merry-making of aristocrat and of peasant. An equally persistent form of diversion has been gambling. The most primitive peoples have their games of chance, while from India and China, as from England or America, come records of long series of protests against the evils of organized gambling. And in every age betting has attached itself symbiotically to almost every available form of contest. Standards of taste and literateness bring now one, now another, amusement to the fore, but the materials of which public amusements have been formed remain the same.

Science and machinery, though increasing their range and specific shape, have hardly added to their number.

Most civilizations have harbored some form of each of these diverse types of amusement, but with varying emphasis. Some amusements are dependent on the cultural situation for their quality or existence, while others have flourished at all times. Empires and despotisms have usually been accompanied by spectacular displays for the lower classes and the restriction of music or literary drama to a small class. A cosmopolitan population gives a touch of exoticism to amusements. Military peoples have emphasized horse races or tourneys and the ideals of physical health. In times of social change amusements take on a restless, shifting, roistering character. There has probably never been a time without its cruel amusements, but excesses of blood lust seem to occur most frequently in societies which are frankly organized on a basis of arbitrary power.

More significant than the coexistence of particular forms of amusement is the place of all amusements in the composition of different cultures. One of the primary changes in the position of amusements occurs in the transition from a simple, well integrated community to a protean, loosely grouped society, urban or rural under urban domination. In the former, amusements rise directly and with spontaneity from everyday activities. They involve the same personal contacts as work or religion. The distinction between work and release from work is thoroughly well recognized in a primitive community, but one activity may serve both purposes. The rhythmic cooperative effort of canoe building partakes of the nature of play; hunting is not only work but sport; the spring earth festival is a serious duty, but its color and fire afford to participant and spectator a sense of moving drama. Athletic contest, games or feast are set apart by a holiday spirit, not by contrast with ordinary forms of activity. All are held together and shot through by religion. One can hardly speak of a social function of amusements in a primitive community. Games may serve as a training for the youth and be caught up into the ritual of initiation; contest and drama help to strengthen group loyalties, to build about the individual a wall of human associations that protect him from the terror of natural forces; but such is also a function of religion and of all the institutional regulations of the community. For the individual amusements have a distinct psychological place;

for the community they are inextricably woven into one pattern of social life.

Most rural communities have preserved something of this closeness of the texture of living. They have generally had neither the leisure nor the wealth to support elaborate entertainments. It is around the wedding or the funeral that such a community creates its celebrations; the husking bee and the quilting bee or the barn raising are important forms of amusement. Even when the merchant has come, bringing with him all the diversions of the fair, or the traveling singer or the Chautauqua makes an annual visit, these but supplement the more essential community amusements. The class privileges or tastes in amusements that always develop in a city are of little importance in such a community. Economic status affects power, of course; but everyone within the community has some share in its festivities. Something of the mutuality of relationship between religion and amusements is usually preserved in such a community. For the peasant of Europe, Eastertide and Christmas with their candles and flowers; for the villages of Japan, the Feast of the Dead when every little stream is gay with its tiny lighted boats floating to the sea; for the American in the small community, the church sociable with its cakes and amateur fortune teller—for each in a different way religion and amusements are associated.

This clustering of amusements about vital community activities has been one of the most enduring patterns for their organization. It appears in East and West alike, among peoples who have never known urban civilization and among groups who have left large cities to establish themselves in new continents. Although it is suffering disintegration throughout most of the Occident by the scattering of communities and the introduction of city amusements into the most remote districts, it can never entirely disappear and must regain its importance with every dissolution of an urban civilization. It is even making its way in an attenuated form into our present industrial society: the community as the social unit for work and play and worship having disappeared, the neighborhood has come to take its place. But the modern self-conscious organized "community," relying upon drama or festival to develop a sense of cohesiveness, can never restore amusements to their original place. Not only does the community movement itself restlessly organize on an international scale, but its very existence depends upon a setting apart of amusements from the rest of

life that gives them a social position very different from that which they had in the older type of community.

It is not, however, only in the primitive or the rural society that amusements develop in intimate association with other forms of activity. The amusements of an aristocratic class are essentially of this nature. The once necessary hunt becomes the sport reserved to the privileged class; out of the preparation for war is developed the tourney; while old and simple games are elaborated for the better diversion of a group with wealth and leisure. But the most characteristic amusements of aristocracies have been those which centered around and developed out of private social gatherings. In China and in India, in Homeric Greece and in imperial Rome, in Renaissance Italy and in eighteenth century France, the feast has been the occasion for elaborate dances, for music, for brief dramatic entertainments, for exhibitions of physical skill by the slaves or retainers of the host. Not infrequently have the members of an aristocratic class been themselves the most accomplished musicians or painters; and, always preserving an elegant air of amateurism, a whole court may devote itself to the writing of poetry or to the half drama of the masque. When a Leonardo turns naturally from the painting of the Last Supper to the designing of costumes and machinery for a court carnival, when that carnival combines drama and fireworks, dances and contests between philosophers, there is reproduced in a highly sophisticated form that closeness of contact of amusements with other activities that is characteristic of simpler communities. The amusements of such an aristocratic group may have a perfection of finish and an intimacy of tone that can be developed on a large scale under no other conditions. But it is also under such conditions that diversion is most apt to defeat its own ends through becoming all absorbing.

Not all of the amusements of an aristocracy remain exclusive; the mediaeval tourneys made place for contests by archers or rural athletes; the English gentleman permitted his private prize fighters to give public performances; the Renaissance nobles vied with one another in the richness of the floats they furnished for the great city pageants. Such provision for the pleasures of the people may be the result of political expediency; it may indicate the beginning of a development of municipal or national rather than class pride. For at some period in its history

almost every aristocracy has turned for fresh diversion to the amusements which have grown up among the other classes. In a society definitely organized on caste lines such a whim may endanger the whole social structure. In seventeenth century Japan, for instance, the increase of popular plays threatened to break down the hard lines of class; the emperor hastily prohibited what plays he could, relegated others to disreputable quarters of the city and forbade the samurai to attend them. But in the more loosely organized societies of western Europe nobleman and lady had always frequented to some extent the arena or the public theater. Indeed it is difficult to tell whether such diversions as bear baiting, the favorite amusement of Queen Elizabeth, or prize fighting, popular with later English monarchs, were originally popular amusements taken over by the aristocracy or were imported from the East by the nobles and gradually spread in favor.

If an aristocracy is to preserve its own amusements and its aloofness to those of the people, it must live outside of the city. For the growth of urban civilization gives to amusements a new character and a new compulsion. City life involves a formalizing and separation of the spheres of activity that set amusements apart in time and space and function from other activities. City amusements are essentially mass amusements. The city regularizes the sporadic drama or festival; it gives the traveling player or clown a permanent stage; it brings together men of all tastes to form a large and restless audience eager for any diversion. The city furnishes the necessary conditions for professionalism. The priest who takes the important part in the religious drama or the traveling player who makes his few coins in remote rural districts is in a sense a professional; but it is only in the city that there develops a whole group of people dependent for their living on their success in entertaining others. In the city organized amusements increase in frequency and variety. The victor in the Olympic games of antiquity, no longer content with an appearance every four years, travels all over Greece competing before audiences well pleased with the increased opportunities to share in the excitement of an athletic contest. The politicians of Rome soon realize that the periodic religious festivals are too infrequent to satisfy the restless city group, and every victorious general takes the opportunity of his return to institute a new holiday with more elaborate processions and combats. Thus the city secularizes amusements,

for although religious festivals never cease to be of importance the original holy day character of gladiatorial combat or chariot race is gradually lost sight of as these diversions become more frequently available. And the city sophisticates its amusements. The wild revel is refined and made subtle; the sun-burned, lee-reddened Dionysus becomes white and delicately beautiful; beside comedy grows up tragedy. But the comedy may also become burlesque. The simpler amusements may be penetrated and transformed by a more searching intelligence or they may be shot through with vulgarity. In the smaller humanized city one is most aware of the rationalization, perhaps the over-subtlety, of amusements; the metropolis, although it shelters all types of amusement, thrusts forward its coarser, strident, exaggerated diversions.

It is the amusements of the city which are characteristically spectacles, for whose presentation great masses of people can be gathered together in a relatively small space; spectacles for the enjoyment of which few common traditions are necessary, which are equally diverting to the man dulled by long hours of work or to the vagabond drifting idly and unattached through the streets. The city does not stifle amusements which require more active participation; it supplants them and relegates them to far corners. In every large city there are little islands of community life, racial groups preserving their pleasures with their traditions, professional groups creating their own amusements. The mediaeval guilds had their special holidays as they had their special saints; modern corporations try to foster a group feeling with an annual picnic or a baseball team. Moreover certain forms of amusement which are not spectacles never lose their popularity. The city furnishes new opportunities for games of chance; dancing on the green gives place to the public dance hall. The fair is in one sense a series of miniature spectacles, but at fair or circus the crowd laughs as heartily at itself as at clown or Punch and Judy show. The carnival too sweeps up into its rhythms every individual within reach. Less elaborate forms of amusement may acquire traditions and flourish. Throughout India and China every city becomes gay in the spring with the multicolored and many-shaped kites, not of the children, but of the elders, eagerly competing according to elaborate rules. Throughout other parts of the Orient the flying of pigeons is an equally popular diversion. Such amusements are overshadowed rather than supplanted by mass spectacles.

The character of urban amusements is to no small degree determined by the conditions of their maintenance. As soon as amusements cease to be community affairs their increasing costs can no longer be met by community contributions. In varying ways they have been met by individuals and groups who have become wealthy through the mechanisms of the social system. No matter what the form of support, the maxim of *panem et circenses* has dominated more frequently than is generally recognized. Monarchs have found circus or wild beast shows as effective as war in stilling unrest. The church has expended part of its tithes for the provision of amusements. And wealthy individuals, seeking favor or freedom from censure, have contributed largely, whether through the offering of prizes, through the erection of a stadium or odeum or by direct subsidy. Public officials have always been peculiarly susceptible to popular demand for amusements. For some hundreds of years the road to public office in Rome lay through lavish expenditures on the popular spectacles of the arena. Many a Roman used his whole fortune for the provision of amusements in the expectation of regaining with interest the sums thus spent when he should come to office. The modern politician contributes less directly, though none the less effectively for his purposes, to the staging of a prize fight or the continuance of illegal but popular diversions. Until recently state support of amusements has generally been thus indirect, the support of officials or members of the ruling classes, perhaps using public funds which they had appropriated. At times, however, the state has contributed more directly: the Greek cities in the fourth and third centuries B.C. supported the athletes who represented them in the intercity contests; the republic of Florence appropriated moneys from the treasury for the city carnival. Somewhat different was the method by which the Tudor government provided for the popular sport of bear baiting. A special tax for the maintenance of the bears was laid on the peasants, who were then admitted to the baitings free of charge.

Whether it be king, politician or wealthy citizen who thus provides for public amusements, it is usually the most popular diversions, those which appeal to the largest number of people, which are supported. Thus it is that city pleasures tend to be rough and spectacular, suited to the understanding of the most illiterate. The greatest common denominator of appeal is seldom very refined in taste. Literary amuse-

ments must find refuge in the privacy of small gatherings, while the physical contest and the crude pantomime gain popular attention. It is only in rare moments of culture, such as that of Athens of the fifth century B.C., or in times when the more popular amusements are supplied by other means, that the donor will support a theater or an orchestra.

Although the compulsion of the tastes of the great masses of people is not lessened when amusements come to be organized on a commercial basis, it is offset by other factors. Not only is the wealthy individual more likely to support the less popular amusements, but the mechanism of business can itself make possible the existence of diversions whose appeal is limited. While it is true that most commercial amusements reach out for ever larger audiences, within the same system the experimental theater, the classical ballet, the string quartet, can exist, not for a small wealthy group alone, but for every person in a city.

The commercial element has for long been of some importance in the organization of amusements. In Rome there arose rival entrepreneurs, owners of great numbers of performers, who bid for the privilege of providing the public spectacles. The amusements of fair and market place have always and everywhere been on a commercial basis. But it is only since the eighteenth century and the establishment of business as the dominant mechanism for the organization of society that one form of amusement after another has taken on its mantle. And as petty commerce has developed into big business, the most typical amusement industries have organized on an increasingly large scale. In the United States there is the industry of baseball, dominated by the major leagues, financial concerns which buy and sell players with a view to success and profits. The manager of a prize fight is a genuine entrepreneur. The sport of racing is financed by the use of the stock exchanges of the world. As a result of successive consolidations there is now but one big circus in the United States. The theatrical industry remains primarily a small scale business; but vaudeville and movie are fast being concentrated in the hands of a few corporations.

Modern invention aids modern business methods in the extension of the scope of amusements. The movie, the one totally new art form or amusement which modern civilization has produced, circles the world in a single stride. It finds its way into the most remote rural districts,

and so long as it remains silent it overcomes all language barriers. Radio and new methods of television indicate the possibility of the penetration of this new dramatic form into the individual home or room. The older forms of amusements too have become international. Baseball has become popular in Japan. No longer are we satisfied with local contests; intercity and interstate games and races must all culminate in international contests.

This internationalism of amusements is fostered by the newspaper and the printing press. Perhaps the most important part of a modern newspaper is its sporting section. Popular international heroes of sport are made by these pages. International contests become front page news throughout the world. In addition many amusements have their special magazines. The existence of such a vast literature of amusements is a new phenomenon. Specific amusements have in other ages developed an extensive preceptorial literature. Late in the Middle Ages the rules of the tournament were written down and carefully formulated; the best methods of breeding cocks, of training falcons or bears, were recorded in lengthy treatises when those sports were old. And with the growth of antiquarianism specific sports and amusements have received their share of research. But modern athletics have developed international rules and traditions in the space of a few years; modern drama has its constant day by day criticism. This great body of comment, though it attempts little social criticism or evaluation, does exercise a directive influence on the development of amusements; it has the power to discourage or condone the worst abuses of professionalism; it may foster or hold back the radical and the new. But most important, it makes it possible for the man who cannot witness game or contest to read of it, talk its language and follow its development.

Thus in our modern civilization all the potentialities of urban amusements have been more completely realized than ever before. Amusements have been made an integral part of the economic system; as such they can be bought any day or night. While the need for diversion from routine is greater than it has ever been, amusements themselves have become part of the routine. Their vicarious character is increasingly emphasized. Indeed the spectator attitude has become so pervasive that it penetrates almost every form of activity. The dance marathon takes its place with the round-the-world race and the national marble contest as a form of

diversion. Record breaking is not a new phenomenon. Plutarch protested against the false emphasis upon it in his time, but never has it been so prevalent as today.

Modern conditions emphasize above all the function of amusements as a stabilizing, unifying force in a society no longer held together by spiritual or community bonds. In earlier civilizations this stabilizing influence was sometimes offset by the danger to order which the gathering of crowds of people always represented. Theater and movie still play upon religious and racial animosities; indeed the potentialities for propaganda are greater than ever before, as chambers of commerce and communist or Fascist leaders well know. But as powerful as the propaganda of the newsreel is the propaganda of the love story. In the darkness of the movie palace political and national differences are forgotten. The very strength of amusements lies in the standardization of tastes which they can effect. Men of totally different racial and work backgrounds speak the common argot of baseball or the prize ring. The language of amusements becomes the truly international language; the assumptions and standards of amusements become the most effective bonds of social unity.

Churches have again and again opposed public amusements, perhaps because of a realization that these may become more important than religion in the setting of standards and the binding together of society. A religious group does not, however, oppose the amusements which it controls. The Catholic church fostered the miracle play at the same time that it was condemning the drama; the most important form of Japanese drama, the "No" plays, was entirely developed and performed by Buddhist monks in an attempt to inculcate moral principles. The great religions of the Orient seem never to have attacked amusements as such; but the Hebraic religions have been traditionally hostile to popular amusements. The early Jewish tribes, like other primitive peoples, had their games and dances and festivities; it was with the introduction of Graeco-Roman games into Palestine that the priests began to condemn as idolatrous and immoral these attractions which threatened to break down their racial exclusiveness. Tertullian in his *De spectaculis* attacks first not the obvious vulgarity and depravity of the gladiatorial combat and the popular farce, but their connection with idolatrous worship. Since they are in honor of pagan gods they become part of the pomp of the devil and so evil for Christians. This charge

of idolatry was repeated by Cyprian, by Chrysostom, even by Augustine, and left its traces on the canon law.

The members of a small sect might well keep themselves apart from the amusements of the world; but when Christianity was suddenly transformed into an imperial religion it became a church of nominal rather than of convinced members. Although at its instance a series of imperial edicts forbidding plays or spectacles on Sunday were promulgated, they were of limited effectiveness. Throughout the Middle Ages much of the wealth and talent of the church went into the support of every form of amusement. It remained for the reformed church to condemn once again; the English Puritan attack of the seventeenth century was carried on with an unequaled bitterness of invective. The hostility was not entirely moral; the extravagance and the foreign airs of the court enraged the honest Puritan as much as its revels; the popularity of masque and play with the prelates of the established church added fuel to his anger; and the general lawlessness of the strolling player increased the zeal for suppression. But it was the old charges of idolatry which were repeated by one of the outstanding critics, William Prynne, in his *Histriomastix*. The Puritan opposition forced James I to issue in 1618 his Declaration of Lawful Sports, the famous order which, while it sanctioned certain forms of amusement, forbade rude and disorderly pastimes on Sundays and holidays; an order which was copied by many of the colonial legislatures of America. With the triumph of Cromwell all plays were for a time suppressed, but even before the Restoration they had crept back, and Sunday prohibitions were never strictly enforced. The opposition to Sunday amusements has lasted longer in the United States than in any other country, and blue laws are by no means obsolete. But particularly in the cities one sect after another is giving up its opposition to dancing, to the theater, even to Sunday amusements. To an ever increasing extent the churches are directing their attention to the moral aspects of amusements, attempting to do away with specific abuses and to provide their own non-commercial diversions.

The state has always been the agency through which reform groups have had to work for the regulation of amusements. The modern state impinges upon amusements at an increasing number of points. Its law courts must settle disputes as to contract and property rights. Since the Middle Ages the governments of

Europe have regulated amusements by means of the power of taxation. The *droit des pauvres*, a percentage tax on the price of admission to spectacles, the proceeds of which are devoted entirely to special funds for the relief of the poor, has been in existence in most European countries since the fourteenth and fifteenth centuries. This and more recent taxes are graduated according to the type of amusement, so that theater and opera are lightly taxed while the burden on public dance halls and race tracks becomes almost prohibitive. In the United States and England, on the other hand, taxation of amusements has been purely fiscal.

The most important form of modern regulation of amusements is municipal. In both Europe and the United States some division of the city government issues licenses for all theaters, motion pictures or dance halls, or amusement concessions; presumably it has the right to make periodic inspections, but except under the sporadic prodding of vice societies this involves little actual supervision. The responsibility of municipal police departments for the enforcement of ordinances and the preservation of public order and welfare is a legal power of far reaching extent; but its use depends upon the attitude of the police force, and in every city profitable and popular, though illegal, amusements continue to flourish. Such a situation is as old as organized government. Indeed no government has ever succeeded in suppressing or curbing really popular amusements. Gambling was forbidden in India as early as the second century B.C. by the Code of Manu, but it was never stamped out; the mime flourished in the latter days of Rome despite the prohibitions of church and emperor; the London corporation drove the theaters and bear dens outside the city limits in the eighteenth century but did not thereby control them; prize fighting occurs in New York City in spite of its illegality; those forms of amusement which are connected with organized vice are driven underground rather than eradicated.

Although the state may fail in suppression it can be more successful in fostering desirable forms of amusements. Most significant for the future development of amusements is the increasing interest which modern governments are taking in the provision of diversions which business has failed to supply. The democratic governments of Europe fell heir to a long tradition of the value of national and municipal opera and theater, and continued to subsidize institu-

tions first founded by the aristocracy as an outgrowth of their own diversions. In the United States and in England municipal drama and municipal concerts have been of slower growth and are still largely dependent on the gifts of philanthropists. But in the sphere known as recreation the modern state is providing public amusements on a large scale. The recreation movement has grown to importance in the past fifty years as part of a reaction to the standardized, mechanized, vicarious amusements of the city, and of a new emphasis on physical health. It has become world wide in scope and in every country is leading to the creation of municipal or national commissions of recreation, which build parks and playgrounds, support athletic clubs or subsidize public festivals and amateur drama leagues.

The characteristic amusements of a great city will always be vast and organized and spectacular. But recreation and community movements point the way to a new form of group activity which will give room for the expression of individual interests and talents. The machines about to be invented which shall produce color and music harmonies in new and gorgeous forms to become the amusements of the future present the same double possibility as that contained in all modern amusements: the most complete world domination of tastes and forms of activity, and the greatest variety of possible means of expression when men have learned to take advantage of them.

ANACHARSIS CLOOTS. See CLOOTS, JEAN BAPTISTE.

ANARCHISM. There is perhaps no other chapter in the history of social-political ideas which has caused so much confusion to the specialist as well as to the general public as the anarchist doctrine. Anarchism covers so many distinct conceptions and tendencies that it is difficult to reduce them all to a common denominator. Besides, it is not so much a definite scientific theory as a mass ideology colored by many emotional and religious elements. It can in general, however, be defined as an attempt to establish justice (that is, equality and reciprocity) in all human relations by the complete elimination of the state (or by the greatest possible minimization of its activity) and its replacement by an entirely free and spontaneous cooperation among individuals, groups, regions and nations. In addition there are certain general propositions and judgments of value with which all representatives of anarchist thought would probably agree. (1) Our unbearable social and moral evils cannot be cured, or even alleviated, by the state, which is necessarily an instrument of domination and exploitation. (2) Human nature is essentially good, if not corrupted by the state and its institutions. (3) All reforms from above are worthless and can only augment our present misfortune. Only the principle of federalism, beginning with the humblest of human relations and ascending to the highest international cooperation, can establish the new society. (4) This new society can only be the result of a revolutionary action (in the soul or in the social-political life) which will destroy the state. (5) Such a revolution, however, would be a complete failure if it built up a new government or any coercive system whatever. (6) The new society of anarchism will not be the product of an inevitable evolution (as is taught, for instance, by Marxist socialism) but will emanate from the natural tendencies of the human soul led by reason and justice and aided by scientific experimentation. (Most of these

principles were codified by the Pittsburg Congress of the American Anarchists in 1883.)

In tracing the origins of anarchist thought there are certain beliefs and doctrines which, though not strictly anarchist in the modern sense, have paved the way for more concise and self-conscious formulations. Many ancient myths of various peoples agree in the belief that a Golden Age preceded the hardships and injustices of the historical state. This conviction found historical expression in the Latin state festival called Saturnalia, which remained an established institution for many centuries and commemorated the old lost liberty and fraternity.

Zeno, the founder of the stoic school, is generally accepted as the first systematic exponent of anarchism. In conscious opposition to the state omnipotence and state communism of Plato, he advocated a stateless society in which perfect equality and freedom would restore the original good tendencies of human nature and establish universal harmony. Carpocrates, in the middle of the second century A.D., became founder of the communist type of anarchism. He believed that not only the state but also private property should be eliminated, and his doctrine combined an unlimited communism with extreme individualism which later developed into sexual libertinism.

In the feverish and exalted religious life of the second half of the Middle Ages, we meet many formulations of a purified Christianity with distinct anarchist tendencies. Especially the doctrine of an ecstatic subjectivism, the claim that the individual can enter into a direct mystic communion with God, by which every sin in him will be extirpated, assumed, in the sect of the Brothers and Sisters of the Free Spirit at the beginning of the thirteenth century, an anarchist tinge. Although this fraternity, denying all state and church institutions and proclaiming the lawless freedom of the divine individual, was cruelly persecuted, it reappeared again and again in the course of the thirteenth to fifteenth centuries and had many followers in France, Belgium, Germany and Switzerland.

Among the sectarians of the Middle Ages we find Johannes Spinner, an outspoken anarchist who advocated principles very much akin to the later doctrine of Max Stirner. There was also Peter Chelčický, a younger contemporary of John Huss and the spiritual forefather of Leo Tolstoy. Against his triumphant Hussite brothers, against the power of the emperor, against the dogmas of the official church, he tried to

establish peace and the freedom and equality of the individual by denouncing bloodshed and repudiating the state as a pagan institution. His chief work, *Siet Wiery* (Net of the Faith), so admired by Tolstoy himself, remained a real Bible of religious anarchism.

Against the growing tendencies of absolutistic monarchy we find many protests, some of them of a distinctly anarchist color. Among the protestants one of the most daring, logical and penetrating, was Étienne de la Boétie who, in his famous discourse on voluntary servitude, attacked the very foundations of despotic power. "Be resolute. Serve no more and you will be free! I do not say that you should expel the tyrant, nor that you should throw him from his throne; only, do not support him and you will see how a colossus, deprived of his base, breaks down under his own weight and collapses. . . ." In the widely spread literature of the Monarchomachs similar ideas found emphatic expression at the end of the sixteenth and the beginning of the seventeenth centuries. Although the chief tendency of this group was not anarchism but a limitation of absolute power, the Protestant and the Jesuit promoters of the idea of tyrannicide approached the anarchist doctrine in making the moral conscience of the individual the supreme judge over the tyrant. It is evident that the psychology by which an individual feels himself authorized to kill the tyrant is not very different from the ideology which entitles the modern anarchist to kill the "bourgeois oppressor." The Digger Movement (see LEVELLERS) in England in the middle of the seventeenth century, led by Gerrard Winstanley, had also a somewhat anarchist character. By the end of the eighteenth century we find in all the leading countries a very rich literature which, though not anarchistic in a proper sense, was an enthusiastic vindication of freedom and the natural rights of the individual. This literature culminated in the writings of the brilliant circle of the French *Encyclopédie* whose editor, Diderot, often expressed definite anarchist ideas. His famous phrase, "Je ne veux ni donner, ni recevoir des lois," became one of the most quoted anarchist slogans.

Two later movements have considerably affected the development of anarchist thought. One was the liberal doctrine in its earlier form, especially as it appeared in the physiocratic school. Their belief in the invisible harmony of society, a brilliant effort to guarantee free com-

petition limited only by considerations of justice, exercised a powerful influence on anarchist thought; the *ordre naturel*, which they so strongly emphasized, and their attempts to liberate economic life from unnatural and unjust shackles, paved the way to Adam Smith and his followers. The liberal doctrine in its later form, through Herbert Spencer and his vehement attacks upon the state and the "coming slavery," also gave new arguments to the anarchist movement. The other force which aided anarchism was the philosophy of Ludwig Feuerbach and his followers, who attacked the accepted religious and metaphysical foundations of the state.

The first systematic exponent of anarchist doctrine was William Godwin, who believed that there are two great evils which cause the present distress and impede the natural perfectibility of our race. One is government, which is inevitably a form of tyranny; the other is accumulated property, which is a monstrous injustice because it constitutes a kind of "mouldy patent" enabling its possessor to exploit the work of other men. Godwin, however, did not reject all kinds of property, but only that originating through exploitation. For the realization of a better society he deprecated all revolutionary actions and did not even advise any kind of social-political reform. Only the propagation of the idea of justice could result in a general enlightenment which would induce the individuals to replace the state by a contractual arrangement of the parishes and to regard accumulated wealth as an unbearable injustice against their fellowmen. Another impetus to the anarchist movement was given by Max Stirner, from the group of the young Hegelians. He continued the revolutionary thought of Feuerbach and undertook the task of demolishing our moral ideas. Society is a pure chimera, and the only reality which can be known is one's own personality; all the rules which limit this individuality are only a fetter which frustrates the healthy development of the ego. The state would be replaced by an Association of Egoists. No economic exploitation would be tolerated any longer, and therefore the dominant type of production would become a free cooperation. Stirner was the first anarchist who advised violent means for the realization of individual rights. The entirely abstract and metaphysical trend of his argument made his influence a very limited one, however, in spite of the propagandistic efforts of John Henry

Mackay. It is interesting to notice that the plan of economic cooperation elaborated by Stirner is very near to that which in the same year was practically realized by the Rochdale Pioneers.

The first man who made anarchism a conscious mass movement was Proudhon. It was even asserted that he was the first to use the word anarchism in our modern sense, but the recent studies of Nettlau have demonstrated that the term was already used in the present meaning in the middle of the eighteenth century. In one of his early works, *What is Property?* Proudhon answered the question with a slogan which became famous: Property is theft. This led to a good deal of misinterpretation, but he was in reality an ardent supporter of private property ("property is freedom") and attacked only usurpation and monopoly. His anarchy was not a contempt of laws but an almost religious attachment to eternal laws. The ideal society represents "freedom in order and independence in unity." To achieve this aim two fundamental revolutions are needed, one directed against the present economic order, the other against the present state. In neither direction was he a preacher of violent revolution, although he regarded such outbursts as inevitable. He believed not in a mass revolution but in a cellular revolution, the economic and moral emancipation of the individual. Proudhon did not attack capital, but only its power to exploit the workers. He saw the real evil of capitalistic society in the sphere of distribution rather than production, and advocated as the fundamental institution of a new order a special type of credit organization, the so-called Bank of Exchange (see LABOR EXCHANGE BANKS). He was convinced that the gratuitousness of credit and the strict mutuality of service provided by this institution would lead to the establishment of free associations of individuals having the same interests and organized on an entirely voluntary basis. Only such associations could eliminate the capitalist economic order and the exploiting state. In one of his later books, however, (*Du principe fédératif*, 1863) he admitted that a total elimination of the state could not be achieved in any conceivable future, and that the main claim of anarchism, therefore, should be restricted to the reduction of the compulsory functions of the state, as far as possible, by a growing decentralization and by a fostering of independent group life.

The influence of Proudhon was very great. The fact that Marxist socialism did not acquire

the same influence in France as in Germany and central Europe is to a large extent due to his gospel. In Germany Moses Hess and Karl Grün and later Gustav Landauer continued, not without success, the propagation of Proudhon's doctrines. The only kind of socialism and anarchism which seems to have had a genuine influence on the Americans of the older stock was a transplantation of the ideas of Proudhon based on freedom and mutual help. The teaching of Stephen Pearl Andrews, William Green and Lysander Spooner developed along the line of Proudhon, and Benjamin R. Tucker amplified his teaching and had a wide circle of followers. It would be interesting to inquire whether and how far the engaging personality of Josiah Warren was influenced by the work of Proudhon. He was the publisher of the first anarchist magazine of the world, and founded an Equity Store in Cincinnati which had a close resemblance to the Exchange Bank of Proudhon.

Modern anarchism assumed new tendencies in the pamphlets, speeches and propaganda of Michael Bakunin, with whom anarchism took a definitely collectivist form. He approved common ownership in land and in other means of production, but retained private ownership in consumption goods and repudiated emphatically the state socialism of Marx. Bakunin's system was based on a threefold foundation: anarchism, atheism and free cooperation of independent groups. Not the conquest but the destruction of the state was the chief aim of his "collectivistic anarchism." But how to build up this new society Bakunin never told. He even repudiated as reactionary all detailed speculation concerning the future. Only two things were perfectly clear in his conception. One was his deep belief in the instinct of solidarity, which led to the conviction that a mankind liberated from the superstition of God and from the corruption of the state will soon find the optimum form of its organization. Thus a hundred years before Bergson he advocated Bergsonian principles: "Only life creates. . . . Science does not create, but only states, describes, the creation of life. . . . Science is the sacrifice of life on the altar of abstraction." The other firm point in his thought was his conviction of the necessity of violence. The revolution, however, according to his point of view, should be a spontaneous work of the masses and not an instrument of political leaders or of disciplined military forces, since political and military domination, he held,

would inevitably lead to a class dictatorship under an organized oligarchy, that is, merely to the formation of another state. His was a semi-mystical doctrine of violence which is similar to the later teachings of Georges Sorel. Although a man of warm heart, he introduced into the anarchist movement a terroristic conception which later more and more assumed the body of a system. His compatriot, disciple and emissary, Netchayev, transplanted the gospel into Russia where it found vehement echo in a soil already permeated by the propaganda of Nihilism. In his revolutionary catechism Netchayev brought the idea of his master to its fullest fruition. There is no crime or brutality which he did not explicitly recommend for the destruction of our corrupted society. Later the doctrine became very much rationalized, and in the theories of Kropotkin, Johann Most, Paul Brousse and others it found a more utilitarian explanation. They argued that the terroristic deed, both individual and collective, is of the greatest importance because it arouses the imagination of the passive masses and awakens the hope of those who suffer under the injustices of the present system.

Since the eighties of the last century anarchism has assumed a more and more rigid communistic form, probably as a result of the mighty growth of Marxist socialism, which appealed very much to the masses of industrial workers. The leader of this movement was Prince Kropotkin, who regarded as antiquated the former types of anarchism, both individualistic and collectivistic, and pleaded for a complete communism. At the same time, however, he rejected all types of authoritarian communism, holding that the state must be radically eliminated by a popular revolution. On its ruins the nucleus of the future society will become the free village community, the commune whose glorious achievements in mediaeval Europe were pictured by Kropotkin with a creative imagination. Each commune will be an independent economic and administrative organization possessing all the means of production and consumption. No system of representation (invention of the bourgeois class) will be necessary under this system. The extreme division of labor, "horrible and injurious to society and brutalizing for the individual," will disappear, giving place to the "integration of labor and production." No compulsory organization will be necessary for the maintenance of the new order, because it will be in perfect

accord with moral law and "free agreements need not be enforced." Among the followers of Kropotkin one of the most remarkable was the famous geographer Élisée Reclus.

Whereas most representatives of anarchist thought regarded religion and religious feeling as a chief impediment to the emancipation of mankind, Count Leo Tolstoy, the great Russian poet and philosopher, came to the opposite conclusion. True religion, as it is embodied in the gospel of Christ, is a complete negation of the state and all its institutions. Pure reason, as manifested in the doctrine of Christ, refuses to cooperate with the state, which is the very negation of love and is a product of egoism and violence. Tolstoy accepted all the main teachings of anarchism with two reservations. One is the unconditional rejection of communism, which would inevitably lead to a new system of state coercion. The other is the strict repudiation of all kinds of revolutionary action based on violence. Only a spiritual revolution, a perfect moral transformation, can make an end to the present system based on war, oppression and exploitation. No violent revolution is needed to achieve this supreme end. Do not cooperate with the state, he taught; refuse to pay taxes, to comply with military duties, to accept the tribunals and the administration of the state, and the whole present unjust society will immediately collapse.

Similar ideas, in conscious support of Tolstoy but founded independently on genuine Hindu religious thought, are propagated by Mahatma Gandhi, the Indian leader, whose doctrine, however, is largely colored by the national struggle of his people against British rule. It is his belief that only by an attitude of passivity towards political life, by civil disobedience, non-cooperation and economic boycott, and not by a violent revolution, can British domination be defeated. These and similar conceptions of religious anarchism are not purely individual interpretations of religious thought, but they seem deeply rooted in the religious convictions of the masses. There are dozens of religious sects all around the world (Doukhobors, Nazarenes, Mennonites) which advocate the same principles of passive resistance to military service.

At the end of the last century a revolutionary movement grew up among certain elements of Marxist socialism and trade union organizations which had many points in common with anarchist tendencies. It attacked the parliamentary

form of later Marxist socialism and tried to demonstrate that participation in bourgeois legislation, the system of cooperation with the capitalist state, corrupts the revolutionary spirit of the working classes. The movement found its philosopher in Georges Sorel, who elaborated a semi-mystical theory of revolutionary violence. Revolutionary syndicalism regards the trade unions as the real nucleus of the future society. They must be educated in such a way that some day they shall be able to take over all the functions of the capitalistic organization. At the same time they must become fighting organizations, saturated with the spirit of rebellion, in order to molest, to irritate and finally to overthrow the capitalist state. Hence antiparlamentarianism, antimilitarism (*q.v.*), direct action (*q.v.*), sabotage (*q.v.*), antipatriotism, "Ca' Canny," the extensive use of political strikes (strikes without economic motive). The latter are regarded as preparatory schools for the final general strike of all workers which will give the ultimate blow to the capitalist system. Revolutionary syndicalism had a strong influence in the Latin countries. At the same time, independently of it, there arose also in the United States a similar movement called Revolutionary Industrial Unionism (*see* INDUSTRIAL WORKERS OF THE WORLD).

This map of the various anarchist currents would not be complete without mention of a certain tendency which is more a moral and spiritual attitude in favor of anarchism than a coherent trend of thought. From the earliest times until the present day a very long list of eminent literary men could be traced who, though remote from political theories, have made acute and passionate statements against the state. The explanation is not difficult. A genuine poet, artist or philosopher will feel every pressure of whatever kind as an encroachment upon the natural rights of his personality, and he will be aware that most of our social pressures emanate from the coercion of the state as a machine. The list of such men, to mention only a few, would include Rabelais, Fénelon, Sylvain Maréchal, Diderot, Lessing, Fichte, Richard Wagner, Nietzsche, Multatuli, Edward Carpenter, Thoreau, Emerson, Walt Whitman, Ibsen. A no less enthusiastic support has been given to anarchism by many gifted cartoonists and caricaturists who denounced the present order of things with mordant satire. A type of anarchist caricature was created by Puget's magazine, *Père Peinard*, and George Adler is

perhaps not wrong when he attributes to this kind of propaganda a great influence on terroristic deeds.

Outside the field of actual anarchist thought there are two important intellectual movements which share the fundamental anarchist attitude to the state. One is the "Liberal Socialism" of Franz Oppenheimer, which would restrict the sphere of influence of the state to a minimum and give the largest opportunity to local autonomy, decentralization, federalism and to the spontaneous economic union of capitalist-producers, liberated from the yoke of capitalism by the elimination of monopolistic landed property. The other is the pluralist school of political thought, which endeavors to demonstrate that there are many associations anterior to the state; that above the law of the state there is the common moral conviction of the society; that the "supreme power" of the state is practically always limited by the power of other associations; that the whole trend of economic evolution tends to discard state sovereignty; that the unified centralized state will disappear and will give place to a cooperation of various economic, cultural and religious associations.

Even a very summary description of the historical development of practical anarchist policy is a matter of great difficulty. Anarchism never became an organized mass movement as socialism did, and there is not even a possibility for such a development. The very essence of anarchist thought precludes organization. The anarchist congress at St. Imier (1872) protested energetically against "the reactionary assumption" of giving to the proletariat a definite program and an authoritative guidance, although continuous persecution of the movement by state authorities often compelled the anarchists to an underground organization. A discussion of the mass movement, therefore, must restrict itself principally to the emphasis of certain important features or some rather typical traits that it displays.

The antagonism between anarchists and communists became an important force of differentiation in the proletarian movement. The first period of the International Workingmen's Association, called the Mutualist Period, was characterized by the predominance of the principles of Proudhon over the Marxist minority. The situation was slowly changed when in 1868 several organizations entered the association which previously belonged to the

Alliance Internationale de la Démocratie Socialiste, founded by Bakunin on a strictly anarchist basis. This adherence led to a short collectivistic period of the International when the followers of Marx and Bakunin were successful in overruling the former Proudhonist attitude and in forcing an acceptance of the claim of nationalization of all landed property (Congress of Geneva, 1868, of Basel, 1869). By this the ice was broken for pure communism, and Marx attacked more and more violently the anarchist wing represented by Bakunin, who in his turn made a violent struggle against the authoritarian "German Communism." The end of the conflict was the expulsion of Bakunin from the International (Congress of The Hague, 1872), but the organization did not survive this amputation because this very congress decided the dissolution of the International, whose general council was removed to New York, where it died silently. Bakunin remained therefore undefeated and was successful in gathering the chief anarchist forces in the Fédération Jurassienne, which became the nucleus of anarchist revolutionary propaganda and regarded itself as the legitimate successor of the dissolved International. As a matter of fact, several congresses were held under the name of the International (the last in Vervier, 1877), but these congresses were not strictly anarchist in their character. Only the congress of London, 1881, and of Amsterdam, 1907, can be regarded as real anarchist congresses of an international character. The Federation of the Jura became a revolutionary center from which anarchist propaganda radiated into all parts of Europe, but it soon found a formidable enemy which checked its influence. This was the regvanized International Workingmen's Association which, after its Congress of Paris (1889), carried on an embittered struggle against the anarchist movement until it broke with it entirely.

The only countries in which the anarchist movement assumed a certain mass importance were France, Italy and Spain, where the labor movement has shown anarchist color leading sometimes to violent excesses, and the state finally felt itself compelled to interfere and crush the agitation by brutal measures and Draconic exceptional legislation. In terroristic attempts against political figures the anarchists of the Latin race had an overwhelming part. Many attempts against the lives of sovereigns were successful, and the terroristic deeds aroused a wave of persecution against the

anarchist movement. This paramount participation of the Latins cannot be explained on purely racial grounds. The chief cause lies in a rigid system of centralization allied with excessive red tape and (at least in Spain and Italy) with a system of pseudo-constitutionalism. Besides, in Spain and Italy the feudal land system made social oppression still more conspicuous. This explanation is corroborated by the facts that under the Austrian absolutism there arose in Vienna a vehement anarchist movement (about 1880) which cost the lives of several government employees, but that later when more civil liberty was given, and especially when a powerful Social Democratic party was organized, the movement lost all its significance. It is manifestly not an accident that the terroristic theory of anarchism was born in Russia, the classic country of feudalism, despotism and bureaucratic abuses. It is an interesting fact that, although European anarchist thought was so conspicuously influenced by its Russian apostles, the movement itself never assumed a greater significance in Russia because other more rigid and centralized political associations, the Socialists, the Nihilists, the Social Revolutionists and the Bolsheviks, were more successful in uniting the revolutionary energies of the country. The anarchist organizations and papers have been completely suppressed by the Bolshevik government during recent years.

In all other countries where a sufficient amount of freedom and constitutional liberty has guaranteed an adequate share of activity and independence to the individual, anarchism never became a dangerous movement. The former extreme liberalism of England and Switzerland toward political refugees did not disturb, even in the most critical period of the anarchist tide, the calm of the citizens, who preferred "to cast ballots rather than to cast bullets." The story of American anarchism seems to corroborate these conclusions. Only the non-violent liberal individualistic type of anarchism had a deep influence on the genuinely American mind, whereas the violent communistic anarchism, transplanted by the German exile Johann Most, appealed rather to the immigrant proletariat. The vehement Haymarket Riot in Chicago (1886) caused the execution of several alleged anarchists, the imprisonment of Most, and the suppression of the anarchist organizations and papers. The murder of President McKinley in Buffalo in

1901 by an anarchist exasperated American public opinion so greatly that the next year a law was passed forbidding anarchists entrance into the United States. In spite of this prohibition, it is recent immigrants from the regions of the "highest social pressure" who seem to constitute the revolutionary ferment in the latest phase of anarchism, revolutionary trade unionism. Nothing demonstrates more clearly the extent to which terroristic anarchism has been repudiated by genuine American public opinion than the fact that even now, and even among intellectuals, the term anarchism is often indiscriminately used to indicate assassins and all kinds of disorganizing forces.

Critics of anarchism attack the theory generally from three points of view. First, they argue the absolute necessity of a coercive organization in any human community. Second, they undertake to show that without violence the destruction of the state is unimaginable, whereas with violence a new state would immediately follow the destroyed one. Third, they argue that the preaching of violence and the application of immoral means destroy those very human tendencies on which anarchism intends to build the new society. To these objections it might be added that the later communistic anarchism of Kropotkin and his followers is a manifest *contradictio in adjecto*. It is evidently a gratuitous assumption that every man will spontaneously renounce the advantages of private property. With this assumption repudiated, it becomes obvious that a communist society must be based on coercive organization.

These arguments, however, do not destroy the whole edifice of anarchist thought. The stateless society is only an ideal vision to the anarchists, and some of them have avowedly abandoned it. Moreover the doctrine of violence or passive resistance is not essential in the system. The fundamental element of anarchism is an extension of classic liberalism from the economic field into all other fields. It is a maximum of spontaneous cooperation based on equivalent exchange, measured on the scale of justice.

This emphasis on justice and liberty (if necessary, above practical efficiency) is surely an important admonition in a society which begins to lose the very meaning of these ideas. Anarchism is an emphatic assertion of the truth that our present mass democracy is not a definite solution of our deepest problems. It is a protest against the growing mechanization

of political life; against the worship of state institutions, which tend unavoidably to become aims in themselves; against the tendency of the increasingly centralized state to standardize all the activities of society and gradually transform not only material production but also art, science, literature and education into a state monopoly under which all minorities will be forced to accept the standards of the ruling group. Anarchism claims that every social relation must be measured by the individual needs involved. It asserts most emphatically that the state is only instrumental in the fulfillment of these needs, as measured on the scale of justice. It is a plea for all those tendencies which lead toward home rule, regionalism and federalism, to the subordination of the present nation states to a broader international unity. It is an apotheosis of the richness of individual and group life as against the growing uniformity and mechanization of our present state.

The ultimate feasibility of such a plan depends upon the answer which we give to the old dilemma so clearly stated by Bastiat: Is it true that the natural economic order is in its very essence antagonistic, that it must inevitably lead to a polarization of society between extreme wealth and extreme misery, or is it rather true that economic life could lead to harmony if liberated from certain artificial obstacles? If the first alternative is true the compulsory regulation of society becomes a moral imperative. If the second, the road is open toward a growing decentralization of the state and a growing intensification of autonomous group life.

ANCESTOR WORSHIP is a term which is still vaguely defined, despite its prominence in all evolutionary schemes since Herbert Spencer. This confusion is to some extent due to the tendency on the part of most sociological theorists to approach the subject with definite presuppositions concerning its origin and development. In fact there are those who maintain that ancestor worship is a stage in the evolution of all religions—that it has been retained in some cases, notably the religions of the Chinese and Japanese; superseded, as in the Semitic, Greek and Roman religions; or not yet attained,

as in the case of many primitive religions. In all these essentially evolutionary schemes of thought ancestor worship is supposed to have developed out of the cult of the dead and the propitiation of their ghosts, particularly the propitiation of the ghosts of deceased members of the family. To understand the nature and the rather peculiar distribution of ancestor worship, however, all such developmental schemes should be kept in the background, if not disregarded.

We may define ancestor worship as the equating of one's ancestors, both remote and immediate, or of persons standing in the place of ancestor or titular household head, with spirits and gods, and the transference to them of all specifically religious acts and attitudes which are usually associated with the worship of the spirits and gods. This would definitely exclude the cult of heroes, whether semi-historical or mythical, among the Greeks and among numerous primitive peoples, particularly the American Indian. Where remote ancestors or kings are regarded as gods, we may or may not have an instance of true ancestor worship. The question turns on the historicity of the deified person and the quality of transference of religious attitudes.

Ancestor worship today has a very specific distribution. It is to be found in marked development among primitive peoples only in certain regions. It characterizes the religion of the Bantu Negroes and of many of the Melanesian tribes, and it is also to be found in certain parts of Asia. With the possible exception of the ancient Peruvians and of the Pueblo Indians in the southwest of the United States, it can hardly be found in aboriginal America at all. Among the Australian natives a strangely confused situation exists because of the peculiar development of their belief in reincarnation. Among civilized peoples the Chinese and Japanese are of course the classic examples of ancestor worshipers. Historically, however, Japanese ancestor worship is an importation from China. True ancestor worship seems therefore to have developed in but few areas and, far from being a universal phenomenon in the history of religions, it seems comparatively rare. This should dispose at once of the numerous attempts made to correlate it with certain types of economic organization, particularly with an agricultural community, or with certain forms of family life.

Among the Bantu peoples we may find the

best illustration of ancestor worship in all its manifestations. Contrary to most theories of the development of religion, the ancestor worship of the Bantu has no connection with festivities associated with the dead, which are so common among many civilized peoples. When an individual dies he joins the family gods and is worshiped as one of them. An ox is immolated over his grave, as is customary when an oblation is made to the gods. The deceased must now be worshiped even by his brother, who may remember all his faults; the dead man has become an ancestor god who must be propitiated and prayed to for protection. Although death has worked no change in his character, his former human attributes in no way detract from the new ancestor's godhead. Like a god he reveals himself to his former relatives through dreams, ecstasy, trance, possession, prophecy and reincarnation. He may assume the form of an animal or be actually reborn in one of his descendants. In the latter case it would appear that no belief in the divinity of such a person exists, for when he ceases to be dead he is no longer divine.

It is characteristic of all forms of polytheism or daimonism that specific functions and benefits are associated with particular gods or spirits. Among the Bantu this role is immediately extended to new ancestor gods. There are two forms of such gods, those connected with public and those connected with private worship. When it is a question of prayers for rain, for the fertility of the land or for that of the herds, prayers are addressed to the ancestors of the ruling dynasty. For specifically private boons, for protection or deliverance from private ills, prayers are addressed to the spirits of more immediate ancestors. There is a point-to-point correspondence between the deceased who have become gods and the older gods of the community. Strangely enough, images of dead ancestors are, on the whole, rare, despite the fact that idols were by no means uncommon in the Bantu area.

Although the ancestor worship of the Bantu is perhaps the most thoroughgoing example of this faith that we possess, that of the Chinese is almost as marked and is of course on a much higher ethical level. But because of this ethical reinterpretation and because since Confucius it has become a sophisticated and officially accepted faith, ancestor worship in China does not give us the same insight into the workings of such a religion as is revealed by the Bantu.

If there were any truth in the widely accepted belief that one type of religion displaces another among primitive people, we should expect to find among the Bantu no other gods than ancestor gods. But even here numerous other gods, obviously older, are duly worshiped.

All the facts at our disposal indicate, therefore, that ancestor worship is essentially of a transitory and unstable nature. The older polytheistic nature worship and animism were always making inroads upon it. Perhaps it is also well to remember that where men can become gods so easily and mechanically these same gods may likewise become men, particularly when we bear in mind the marked association of ancestor worship with the belief in reincarnation in Africa, Melanesia and Japan.

Whether ancestor worship has any marked influence on so-called progress and whether it in any way circumscribes thought and action and makes for rigid conformity, is more than doubtful. The stagnation of Chinese civilization has always been cited as an example of its deleterious effects. But this can be explained far more adequately in other ways. If the customary explanation were indeed a true one, the Japanese and the Bantu civilizations should exhibit the same traits as the Chinese. Yet emphatically they do not. The deification and the milder form of this same phenomenon, the veneration of one's ancestors, are recurrent phases of religious life intimately bound up with specific psychological tendencies of the human race that are called forth by certain social and economic situations.

C., *The Soul of the Bantu* (Garden City 1928), and the famous work of Canon Henry Callaway, *The Religious System of the Amazulu* (Natal 1870).

ANDERSON, ELIZABETH GARRETT (1836-1917), English feminist and a pioneer in opening the medical profession to women. In

the late fifties, when the small group of English feminists divided among themselves the tasks of enlarging the economic, social and political opportunities of women, Elizabeth Garrett chose to make the initial attempt to obtain a medical degree. Dr. Elizabeth Blackwell's London lectures of 1859 and the counsel of Emily Davies helped her in this decision. Admitted to some medical lectures through the roundabout method of service as a nurse she showed unexpected proficiency in preliminary examinations only to find herself confronted by the refusal of all medical colleges to permit her to matriculate. The charter of the Society of Apothecaries, however, made her exclusion impossible. In 1866, equipped with an apothecary's license, her name placed on the British medical register, she founded in a working class district the first woman-staffed dispensary for women. This was later known as the New Hospital for Women and after her death was called the Elizabeth Garrett Anderson Hospital. In 1870 it was through the help of her patients' husbands that she was elected as the first woman member of the London School Board. By this time she had obtained in Paris the medical degree denied women in England. For many years she and Dr. Blackwell remained the only women on the British medical register, and it was not until after a widespread agitation in which they both participated that some of the obstacles to the medical education of women in Great Britain were removed. She aided in establishing the London School of Medicine for Women in 1874 and was on its staff as teacher and dean for almost thirty years, serving at the same time as senior physician of the New Hospital. In 1908 she became England's first woman mayor, holding office in that capacity in Aldeburgh, Suffolk. In an age which not only doubted women's capacities but frowned on higher education for women as interfering with their "natural functions," Dr. Anderson's marriage (1871) and children may perhaps have been as important factors in her influence as her high professional repute.

ANDERSON, JAMES (1739-1808), a pioneer in scientific agriculture. Anderson was a native of Hermiston, near Edinburgh, and the son of a farmer. Both his parents died while he was young, leaving him a holding which he

worked for some time with successful results, thanks to his diligent study of agricultural chemistry and the employment of improved methods and implements. Later he removed to Aberdeenshire, where he earned fame as a ready writer on high farming, but in 1783 he retired from practical agriculture and settled in Edinburgh. He devoted many books and pamphlets, as well as a great deal of magazine and newspaper writing, to agricultural questions, including leases and land tenure generally, the Corn Laws, emigration, the drainage of bogs, the construction of dairies, etc. He also took great interest in the Scottish fisheries, and made a survey of them at the request of Pitt. Although in general favoring free trade, he advocated state protection for the national fisheries. He may claim to have laid the foundations on which Malthus and Ricardo built their doctrines of rent. In one of his earliest writings he speaks of rent as a premium for the cultivation of the richer soils, reducing the profits of the cultivators to an equality with those of the cultivators of the poorer.

W. H. DAWSON

Important works: *Observations on the Means of exciting a Spirit of National Industry* (Edinburgh 1777); *An Inquiry into the Nature of the Corn Laws, with a view to the new Corn Bill proposed for Scotland* (Edinburgh 1777), in which he anticipated Ricardo's doctrine of rent; *An Inquiry into the Causes that have hitherto retarded the Advancement of Agriculture in Europe* (Edinburgh 1779); *An Account of the present state of the Hebrides and Western Coasts of Scotland* (Edinburgh 1785); *Observations on Slavery, with a view to its effects on the British Colonies in the West Indies* (Manchester 1789); *A Calm Investigation of the Circumstances that have led to the Present Scarcity of Grain in Britain* (London 1801).

ANDERSON, WILLIAM C. (1878-1919), British labor leader. The son of a Banffshire blacksmith and apprenticed to a chemist, Anderson was one of the younger members of the group of self-educated working class intellectuals associated with Keir Hardie and Ramsay MacDonald in the inner councils of the Independent Labour party. As national organizer for the Shop Assistants' Union he brought it close to other elements in the labor movement. It was in connection with his work for the union that he met Mary Macarthur, whom he married in 1911 and whose work for the Women's Trade Union League he aided with his

executive and literary abilities. Anderson's eloquence as a speaker and his skill in debate made a parliamentary career inevitable and, after unsuccessfully contesting two elections, he became M. P. for Attercliffe in 1914. At the same time he was chairman of the executive committee of the Labour party. His excellent judgment, executive ability and personal popularity helped him to steer the Labour party through the difficult years of 1914-16, and marked him as a promising candidate for the leadership of the political labor movement. He opposed the entrance of labor into the coalition government in 1915 and loyally supported the "international" policy of the I. L. P. during the war. He fought to preserve civil liberties, to abolish military conscription and to save the workers from industrial conscription under the Munitions Acts. Together with the other pacifist leaders he was deprived of his seat in Parliament by the "khaki election" of 1918.

Feb. 27, March 6, March 13, 1919; Labour Party (Great Britain), *Report of the Annual Conference of the Labour Party*, for the years 1914-19, of which the last contains an obituary notice; Independent Labour Party (Great Britain), *Report of the Annual Conference*, for the years 1908-19.

ANDLO, PETER OF (Andlau, Petrus de) (c. 1425-80), jurist and political theorist. He was born in Alsace, studied at Heidelberg and Pavia, and became cleric and professor of canon law at the university in Basel, which was founded with his cooperation. His chief work is the *Libellus de caesarea monarchia*, or *De imperio romano-germanico libri duo* (ms. circa 1460, published Strasbourg 1603), the first exposition of German imperial law. The first part, which is a historico-philosophical treatise, begins with political doctrine, discusses the question "republic or monarchy?" and explains the transition from the Roman to the German *imperium*. The second part deals with the German public law of his time, with princes and the king, with the nobility and the Reichstag. Peter of Andelo built on the doctrines of Thomas Aquinas, Aeneas Silvius, Landolph de Columna, Lupold von Bebenburg, Jordanus von Osnabrück and Felix Hammerlin. In the struggle between emperor and pope he acknowledged the pope's as the superior right; he also still believed in the Donation of Constantine, but he tried to reconcile the two powers. As a loyal adherent of the imperial idea he dedicated

his book to the emperor. His is a work of reform, full of ethical pathos, which urges especially the acceptance of the Roman law. He wrote (1471-78) a second book, advocating moral reform of the clergy, *Tractatus de canonica clericorum secularium vita*, printed as appendix ix in Hürbin's biography of Andelo.

EBERHARD VON KÜNSSBERG

Consult: Hürbin, Josef, *Peter von Andlau* (Strasbourg 1897).

ANDRÁSSY, GYULA, GRÓF (1823-90), Hungarian statesman. As a young man Andrassy was an enthusiastic supporter of Louis Kossuth, in opposition to the interest of his own class, and took an active part in the Hungarian War of Independence of 1848-49. After the disaster of Világos he escaped from the Austrian authorities and was hanged in effigy. As a political émigré he lived mostly in Paris and London, where he familiarized himself with the workings of the modern state. After his return to Hungary in 1858 he assisted Ferenc Deák in preparing the way for the solution of the Hungarian question. In 1866, appointed president of the parliamentary subcommittee in charge of the elaboration of the Compromise (*Ausgleich*) with Austria, he conceived the idea of the "delegations," a quasi-legislative organ of control set up to supervise the administration of the joint affairs of the monarchy.

Andrassy was appointed the first Hungarian constitutional prime minister in 1867, and he carried on a spirited campaign against the centralizing policy of Hohenwart's Austrian government. On the resignation of Chancellor Beust in 1871, Andrassy became minister of foreign affairs. He was opposed to Count Beust's anti-German policy and frustrated the proposed *démarche* of the powers in 1875, which was to be addressed to Berlin on behalf of France. He made the monarchy adhere to the Alliance of the Three Emperors of Austria-Hungary, Germany and Russia, and was chief plenipotentiary at the Berlin Congress, where he received the authorization of the powers for the occupation of Bosnia-Herzegovina by the Austro-Hungarian army. The policy there pursued necessitated the reorientation of his attitude toward Russia. He signed the Austro-German defensive-offensive alliance on October 7, 1879, and resigned the following day. His book *Az 1867-iki Kiegyezésről* (The Compromise of 1867) (2nd ed. Budapest 1896) is the most significant commentary on that much discussed document.

To Andrassy's Near Eastern policy (expressed in the famous "Andrassy Note") and his anti-Russian orientation consequent upon the Bosnian crisis, recent historical criticism assigns a part of the responsibility for the complications leading to the World War.

The speeches of Andrassy were collected by Béla Lederer in *Grof Andrássy Gyula beszédei* (2 vols., Budapest 1891-93).

EMIL LENGYEL

Consult: Wertheimer, Eduard von, *Graf Julius Andrássy; sein Leben und seine Zeit*, 3 vols. (Stuttgart 1910-13); Andrassy, Gyula, *Bismarck, Andrassy és Kortársai* (Budapest 1913), tr. as *Bismarck, Andrassy and Their Successors* (London 1927).

ANDREAE, JOHANN VALENTIN (1586-1654), German humanist, clergyman, educator and philanthropist. He is chiefly significant for his *Reipublicae christianopolitanae descriptio* (Strasbourg 1619, Leipsic 1706, tr. by F. E. Held, New York 1916). The most outstanding features of this work are his scheme for an artisan democracy; his project for a system of education run as a miniature republic and manned by instructors who are "the choice of all the citizens," the child to be taken from the age of six to early maturity and the instruction to be carefully graded in eight departments; his emphasis upon religion; his complete dependence on widespread investigation and on scientific laboratories; and his desire for "light" on the part of the citizens. Andreae's *Christianopolis* considerably influenced the utopias and other literature of his century. His educational ideas resulted in agitation for better educational systems both on the continent and in England; and his outline of a plan for a "college" or society of fellows for scientific investigation, combined with his emphasis upon laboratories and investigation, was the germinal idea that developed eventually into the Royal Society.

Andreae has also been credited with exerting a great influence on the development of Rosicrucianism and through it on Freemasonry. The *Fama fraternitatis R. C., das ist, Bericht der Brüderschaft des hochlöblichen Ordens R. C.*, which appeared anonymously in Cassel in 1614, has been attributed to Andreae. With its admixture of pseudo-science, Christian piety, mysticism and anti-orthodoxy, and motivated as it was by the desire for a general reformation of the whole world, this book attained a wide circulation, especially among the followers of

Paracelsus, Böhme and Valentin Weigel, and created a sensation throughout all Europe.

Jahrhunderts und sein Erziehungsideal* (Würzburg 1913); Mumford, Lewis, *The Story of Utopias* (New York 1922) p. 81-99; Kvačala, J., "J. V. Andrea's Antheil an geheimen Gesellschaften" in University of Yuriev, *Acta et commentationes*, vol. vii (1899) no. 2; Schneider, F. J., *Die Freimaurerei* (Prague 1909) p. 85-102.

ANDREAE, JOHANNES (c. 1270-1348), the most influential canon law writer of the fourteenth century. He became a professor at Bologna about 1303. His tenure of this influential chair for almost half a century gave him a post of vantage which he used so effectively that he came to be known as *fons et tuba juris*. Andreae's talents were especially fitted to the stage of development which the canon law had reached. He had neither constructive originality nor interest in the philosophic aspects of law, but was gifted with enormous industry, remarkable power of assimilation and facility in writing. Although the formative stage in the development of the canon law had passed, no one had yet reduced to order the mass of new juristic material which had accumulated in the half century since the *Aurea summa* of Hostiensis. This was the life work of Andreae, which he accomplished in his four principal works. His *Novella . . . in decretales Gregorii IX* supplanted the treatise of Hostiensis as the definitive commentary on the Decretals. His two glosses on the "Sext" and the "Clementines" became the authoritative interpretations, the *glossa ordinaria*, for those enactments. Finally in his *Additiones ad speculum Gulielmi Durantis* he brought that great work on procedure down to date and filled in the gaps with new matter. Andreae's method was essentially one of balancing all the existing authorities. He displays an unquestioning respect for the authority of the legislator, which made him an extreme champion of the claims of the papal power.

JOHN DICKINSON

Works: For a list of the numerous editions of Andreae's works, see the catalogue of the Bibliothèque Nationale.

ANDRÉE, RICHARD (1853-1912), German geographer, folklorist and comparative anthropologist. He was the son of Karl Andrée, founder of the geographical-anthropological weekly *Globus* (published 1862-1910). In 1873 Richard Andrée founded the geographical establishment of Velhagen and Klasing in Leipsic, and from 1891 to 1903 he edited the *Globus*. Even before Ratzel, Andrée devoted himself to comparative ethnological studies. Impressed by the similarities which he observed in the traditions and usages of geographically distinct peoples, Andrée juxtaposed in a number of series certain cultural phenomena such as the lucky day, the evil eye, mourning mutilations, names of persons, standards of value. He was not dismayed by the fact that the cultures he thus compared were sometimes located on different continents and were on the whole dissimilar. The diffusionist theory had not yet been developed, so Andrée was forced to conclude, although not without some misgivings, the independent origin of similar cultural traits. He subscribed to the theory that the similarities are explained by the essential sameness of the human mind and the consequent uniformity of cultural progress. He published also several important studies of folklore and a number of statistical-geographical works.

R. THURNWALD

Important works: *Ethnographische Parallelen und Vergleiche* (Stuttgart 1878); *Die Flutsagen* (Brunswick 1891); *Die Metalle bei den Naturvölkern* (Leipsic 1884); *Anthropophagie* (Leipsic 1887); *Braunschweiger Volkskunde* (Brunswick 1896-1901); *Votive und Weihegaben des katholischen Volkes in Süddeutschland* (Brunswick 1904). ANDREWS, ELISHA BENJAMIN (1844-1917), American educator. He was in turn soldier in the Union army, student at Brown University and at Newton Theological Seminary, Baptist minister, student in Europe, president of Denison University, professor at Newton Theological Seminary, professor at Brown University, professor at Cornell University, president of Brown University, superintendent of schools in Chicago and chancellor of the University of Nebraska.

His contributions to the scholarship and public opinion of his time were many and important. They took the form of sermons, addresses, articles, translations from the German, and books dealing chiefly with history and economics. In all his speaking and writing there were clarity, vigor, human sympathy and unremitting search for philosophic understanding. Andrews was avowedly of the type which its opponents call "radical." In the midst of a financially solid Rhode Island he was a down-right advocate of free silver. The founding of the Woman's College in Brown University gives indication of his zeal and daring in furthering the education of women. He was likewise a pioneer in the establishing of extension courses for the general public, and when the *Cosmopolitan Magazine* projected a scheme for popular college education his imagination was fired by the proposal and he was eager to share in its realization.

The presidency at Brown came when Andrews was at the summit of his powers. He was notably successful at the two points at which alone it is essential that a president should succeed. First, he gathered, held together and led a faculty which was in quality far out of proportion to the funds provided for its payment. Second, in a community whose interests and prepossessions were vaguely or clearly hostile he dominated and swept its student body into the currents of scholarship and moral intensity.

ALEXANDER MEIKLEJOHN

Consult: Meiklejohn, A., Freedom and the College (New York 1923) p. 49-67.

ANDREWS, STEPHEN PEARL (1812-86), American philosophical anarchist. He was identified chiefly with formulating a scheme of universal order based on "sovereignty of the individual." He called it "integralism" and considered it as scientific as Newtonian law. A utopian in a day of utopian experiment, he found practical expression of his theories in the communities of Josiah Warren and Fourier, whom he regarded as the greatest of social prophets. He believed naively in the speedy universal realization of a natural scientific social order without government, law, marriage, the family or punishment. Economic salvation was to be achieved by equal wages in industry run on the principle of "cost as the limit of price," with labor notes as credit and exchange. He pushed his ideas to grandiose lengths, prophesying the ab-

olition of disease and death through the power of belief. The "Pantarchy" of the "Infinite Republic" was to be directed by the most advanced intelligences, who would create "God." He had a considerable following among the utopian-minded, but his disciples were unorganized and his pedantic works reached only their first limited editions. In earlier years he was known widely as a passionate abolitionist, as the chief exponent of the Pitman shorthand system, which he introduced from England, and as the inventor of a universal language.

ROGER BALDWIN

Important works: Basic Outline of Universology (New York 1872); Love, Marriage and Divorce, a controversy with Horace Greeley and Henry James (Boston 1889); The Science of Society (Boston 1895); The Church and Religion of the Future (New York 1886).

ANGARY. In early times in the East the term angary, *jus angariae*, was applied to the taking over for public use of means of land transportation. The term was later applied to the similar taking over of means of transportation upon the water. Such action in early days was not always confined to times of war or based upon absolute necessity, but was taken sometimes in order that the king's journey might be more easy, or that an exploring expedition might not be delayed.

Writers in the seventeenth and eighteenth centuries referred to angary as a recognized right but one that involved adequate payment for the service rendered. Gradually treaties began to be made which regulated the practise and which provided that the right of angary should not apply to persons. The treaties sometimes related the right of angary to embargo. The seizure of neutral vessels by Napoleon in 1798 for transport of troops to Egypt was classed as angary. In 1870 Prussians seized and sank six English vessels in the Seine in order to prevent movement of the French forces and Bismarck advanced the claim that it was under the right of angary. Many treaties in force in 1900 admitted the existence of the right of angary, and of about fifty treaties referring to angary before 1900 only about one third are unfavorable. Of the five treaties since 1900 which mention this right three are unfavorable. Article 5 of the treaty of 1902 between the United States and Spain provides as follows: "Furthermore, their vessels or effects shall not be liable to any seizure or detention for any public use without a sufficient compensation, which, if practicable, shall be agreed upon in

advance" (33 U.S. *Statutes at Large*, pt. 2, p. 2105, 2108). In 1907, at the Second Hague Peace Conference, the seizing by belligerents of neutral railway material within belligerent territory was regarded as analogous to the right of angary. The right of angary was, however, beginning to be regarded as obsolete before the World War, and Article 494 of the British Regulations and Admiralty Instructions (vol. i, 1913, p. 191) provided that if a neutral British merchant ship were "coerced into the conveyance of troops," etc., the senior naval officer should remonstrate or take "steps to assure her release."

During the World War there occurred a marked change in the drift of opinion and practise. Turkish vessels were taken over by Great Britain in 1914, and in a British note to the Netherlands, March 21, 1918, it was said: "After full consideration the Associated Governments (the United States and Great Britain) have decided to requisition the services of the Dutch ships in their ports in the exercise of the right of angary." The Dutch government denied the right but the ships were retained, used and returned. Charter hire was paid and also indemnity in case of damage or destruction.

There has been much discussion as to the existence of the right of angary. Germany called the practise "a strange violation of right," while the French Minister of Marine on November 18, 1917, declared angary is lawful "in presence of imperative and urgent need for the national defense and in absence of contrary treaty stipulations."

E., "Law of Angary" in *American Journal of International Law*, vol. xiii (1919) 267-301; Great Britain, Parliament, "Miscellaneous Paper 11 (1918) Cd. 9025" in *Sessional Papers*, 1918, vol. xxvi (Accounts and Papers, vol. xii) 747-58.

ANGAS, GEORGE FIFE (1789-1879), British colonizer, "the father of South Australia." He was born in Newcastle-on-Tyne and inherited from his father a profitable shipping business. In 1832 he became interested in the scheme to settle South Australia on the Wakefield plan,

by which land was to be sold at a "sufficient price" instead of being given away. The money thus obtained was to be devoted to public works and to subsidizing the emigration of carefully chosen laborers. Parliament approved the planting of the colony (1834) provided sufficient land could first be sold. When it became apparent that not enough land could be sold at £1 an acre, Angas and two friends bought the unsold 14,000 acres at 12/- an acre and floated the South Australian Company to develop this and other lands. For the next sixteen years Angas worked unceasingly in London to carry the colony through its infant troubles. He sent out many shiploads of emigrants, including six hundred persecuted Lutherans from Prussia. He founded the South Australian School Society as well as two banks to handle Australian trade. In 1851 he went to live in the colony after having played an important but inconspicuous part in the formation and the passage of the South Australian constitution. In 1838 Angas heard of French plans to occupy New Zealand and successfully urged the British government to forestall this action.

ANGELL, JAMES BURRILL (1829-1916), American educator and diplomat. He was graduated from Brown University in 1849 and after spending several years in travel and study in Europe he returned to Brown as professor of modern languages. In 1860 he left to become editor of the *Providence Journal* and in 1866 accepted the presidency of the University of Vermont. In 1871 he was appointed president of the University of Michigan, which he raised from a little known institution to one of the strongest state universities in the country. With his administration are associated the development of the university's virtual independence of the legislature in questions concerning finance; also the accrediting system, elective studies, the study of education, graduate and summer schools and improvement in medical, dental, engineering and architectural education. In the history of higher education Angell ranks with Presidents Eliot, Gilman and White. His chief strength lay in his broad conception of a democratic system of public education. He retired as president emeritus in 1909 and died at Ann Arbor in 1916.

Opportunities for public service in another direction came in 1880-82 when he was minister plenipotentiary and chairman of a commission to revise the treaties with China, especially those bearing on Chinese immigration to this country, a task performed in an unprecedentedly short time. In 1887 he was a member of the Canadian Fisheries Commission and in 1895 chairman of the Deep Waterways Commission. In 1897-98 he was minister to Turkey.

ANGIULLI, ANDREA (1837-90), Italian philosopher and educational theorist. He was professor of pedagogy at Bologna and Naples and the most vigorous systematic writer of the Italian positivist school in the political-pedagogical field. As a young man he was influenced by the liberal Catholic thought of Gioberti, then by the neo-idealism of Spaventa and was thus led to Hegelianism. His first book, *La filosofia e la ricerca positiva* (Naples 1868), revealed him as a positivist whose conception of a scientific era was derived from the philosophy of Comte. Although Angiulli's position was between those of Mill and Littré, giving exclusive place to neither man nor nature, he never, as Gentile has pointed out, proceeded beyond the recognition of the necessity for superseding positivism. His doctrine was substantially an expression of scientific mysticism; it postulated a cosmic activity which man creates by his thought and a mysterious harmony in things which guides them through the various forms of life in a continuous progression which becomes conscious in man. In this philosophy man becomes the liberator of humanity, dominating the real world through science and controlling it through perpetual, insatiable research. Without revolution or reaction he can ameliorate his condition by the transforming power of criticism. Such "reconstitution of the social organism depends upon the mental reconstitution of all the organisms that compose it." The state can be made the organ of the necessary scientific education. The state as educator claims every field: physical, intellectual, moral, aesthetic, religious, economic, civil, political. But since the solution of all problems can occur only in the course of

centuries, the state is essentially the guarantor of liberty to future generations. The state must seek to introduce the higher achievements of science into the lower cultural strata in order to prepare all minds for the understanding of truth. This education will exclude all theological dogmatism, and religion, reduced to the subject matter of history, becomes the object of science, not a matter of precept. For Angiulli the ideal program of study is limited to science. He even maintained that the only true spiritual interests of the child consist in knowledge of the objective world. Indeed, to him imagination meant nothing and both aesthetic and religious education were irrelevant. His pedagogy, as systematized in his works, *La pedagogia, lo stato e la famiglia* (Naples 1876) and *La filosofia e la scuola* (Naples 1888), held undisputed sway in Italy until 1900.

GIUSEPPE LOMBARDO-RADICE

ANIMAL PROTECTION. Although history and literature record the affections of individuals for animal pets, no organized movement for animal welfare developed until the nineteenth century. The nineteenth century sentiment for animal protection, like the humanitarian movements for the abolition of slavery and the amelioration of the situation of submerged elements of the population, traces its intellectual ancestry to eighteenth century rationalism. Denial of a special divinity to man cleared the way for recognition not only of brotherhood to one's fellowmen but also of kinship with the animal world. The sentiment for animal protection had always existed in particular individuals; the rationalization of the sentiment developed in the late eighteenth and early nineteenth centuries, when it found an earnest propounder in Jeremy Bentham; the impetus to organization and legislation for animal protection was a side aspect of the general humanitarian activity of the time.

The movement for animal welfare operates in two fields—the legislative and the institutional. There is a close relation between the two, since animal welfare societies are usually instrumental in the enactment of animal welfare legislation and are usually the agencies for its enforcement. Animal welfare legislation may be classified as: first, statutes penalizing

cruel treatment of animals (wanton cruelty, failure to care properly for individual animals or to provide suitably for commercial transportation, fashionable or sporting misuses of animals and vivisection); second, statutes covering the organization and activities of animal protective societies and giving their agents police powers; and third, statutes permitting or compelling the instruction of humane principles in public school systems. Game laws, wild life preservation laws and bird sanctuary laws save birds and animals from the guns of hunters, but the purposes of these laws are not purely humane; often the regulation is intended for the benefit of the sportsmen themselves.

Choice for an arbitrary date for the commencement of organized activity for animal welfare may be divided between 1822, when the English "Martin's Act" for animal protection was passed, and 1824, when the English Society for the Prevention of Cruelty to Animals was formed by Richard Martin. The progress of the animal welfare movement has been most marked in England, in the British dominions and in the United States. It has made slower progress in the Latin countries, where it has never succeeded in enlisting the support of the Catholic church.

The first German society was formed in Dresden in 1839. A Paris animal protective society was formed in 1845, and one was organized in Vienna in 1846. The American S.P.C.A. was organized by Henry Bergh in New York in 1866. By 1929 there were in England 1679 branches and auxiliaries of the Royal S.P.C.A. American societies in 1928 numbered 537. The funds of the English societies are drawn exclusively from endowments. Many of the American societies receive, in addition, public funds. In some states, notably in Colorado and in Wisconsin, animal protection has been made a state function.

The purpose of the earlier animal welfare or protective societies was to enforce the statutes against cruelty to animals. Agents and officers of the societies made arrests and prosecuted offenders. As the animal welfare societies of the larger cities grew stronger and richer, the original pressing demand for their activity as prosecutors in individual cases of cruelty declined. They have never been able to relinquish this function, but more and more they have been able to supplement animal protection by animal welfare activities. They have erected

watering troughs for horses at convenient city locations, established animal hospitals, provided animal shelters to care temporarily for strays and to dispose of such as are not claimed by owners, and engaged in campaigns of education among adults and children to inculcate in them a love for animals. In many cases some or all of these distinct functions are carried on by a single society. The tendency in large cities, however, is toward specialization and separation of functions.

The American animal welfare movement differs in one important particular from the animal welfare movements in other countries; it is often amalgamated with a parallel movement for protection of children from cruelty. Although in most of the larger American cities child protective activities are carried on by independent organizations—societies for the prevention of cruelty to children—334 out of the 537 American humane societies combine child protection and animal welfare work. This combination of functions is not always fortunate, since the two activities demand different techniques, and according to the dominant interest of an organization one activity or the other—usually child protection—is often neglected. In communities where human interest is not sufficiently developed to maintain two independent organizations, however, the combination of activities is the only practicable solution.

In England the Royal Society for the Prevention of Cruelty to Animals is a national organization, operating through branches and auxiliaries. The American humane societies are local organizations. Unity of animal welfare activity in the United States has been achieved through federations, nationally through the American Humane Association, founded in 1874, and through state federations in eleven states.

Antivivisection—opposition to the use of animals in scientific experimentation—represents a radical aspect of the animal protective movement. In England it has consistently been part of the program of the S.P.C.A. Antivivisection sentiment was the impetus for the formation of many of the German protective societies. In the United States the animal protective societies have rigidly dissociated themselves from the antivivisection movement, leaving this field to an independent group of antivivisection societies. The legislative accomplishments of the movement in England and in the United States have been the licensing and limitation

of animal experimentation rather than its abolition.

ANIMAL PSYCHOLOGY. See COMPARATIVE PSYCHOLOGY.

ANIMAL SOCIETIES. Agglomerations formed by animals are to be distinguished as associations (mere collections) and societies (organic wholes). Associations are chance gatherings of animals brought together in certain places by an external factor (insects on a lamp, flies on a piece of meat, lice on a tree branch, game at a spring). Among men, according to this definition, those persons form an association whom accident brings together in a railway coach, in a theater or in a street crowd. In contrast to this, societies are always held together by an internal factor which propels the individuals toward one another and keeps them bound together—by social instincts which are subjectively manifested in man as the need of companionship.

We may divide animal societies into mateships, families and herds. To the last named belong not merely mammals but also swarms of birds and fishes and "states" of bees, ants and termites. Social life always involves among animals a certain degree of brain development; on this account societies are to be found only among those animal species and categories of the zoological system that are most advanced in bodily organization (among mollusks, cuttlefish; farther on in the scale, arthropods, especially insects; and still farther on, vertebrates).

Among many of the lower animals there are no individual sex relations, but what occurs is an emission of sex substances by both male and female into the water where the fertilization of the egg by the sperm follows. In the case of other types among the lower animals, however, a coition does indeed occur, but the sexual act takes place between the sexes without rule, several or many times; that is, there exists a state of promiscuity. We speak here of promiscuity

as the general rule, for it is, in the absence of organized mateship, the normal behavior of these species of animals. The higher we ascend in the zoological scale, the more do instances accumulate in which there emerges a psychic union of the sex partners for longer or shorter periods, or what we must call real mateship. This union takes place not through external factors but through internal causes contained in the psyche of the individuals concerned—through the instinct for mateship. Among birds and mammals permanent mateship is the norm from which only a few species diverge.

The forms in which animal mating appears are: monogamy (one male mated with only one female); polygyny (one male with his "harem," that is to say, two or more females); and polyandry (one female with two or more males). Polyandry is rare in the animal kingdom (as also in man); when it does occur among animals it is always due to the fact that the female sex surpasses the male in bodily size. Monogamy and polygyny are found both as solitary mateships and as mateships within a herd—that is to say, in the first case the mating couple or the male and his harem segregate themselves from their fellows; in the latter case, however, we find monogamous or polygynous mateships within larger herds. Further, monogamous or polygynous mateships either last during one breeding season or are formed for longer periods and sometimes for a lifetime. Accordingly we may distinguish seasonal mateships and permanent mateships. It goes without saying that it is difficult for an observer to determine in the case of wild animals whether individuals are mated for a season or permanently.

According to what has been said we may distinguish nine different categories of mateship: solitary polyandrous mateship (certain worms and spiders); solitary monogamous seasonal mateship (a few beetles and fishes, some amphibians and reptiles, mammals of prey, such as martens, cats, lions, jaguars, foxes, wolves and bears); solitary monogamous permanent mateship (many birds, rhinoceroses, orang-utans); monogamous seasonal mateship within a herd (many birds); monogamous permanent mateship within a herd (many species of parrots, gorillas); solitary polygynous seasonal mateship (buffaloes, elephants, many deer, antelopes, wild sheep, wild goats); solitary polygynous permanent mateship (domestic fowl, South American ostrich, guanacos, vicuñas, primitive wild horses, zebras, wild asses,

kangaroos, apes); polygynous seasonal mateship within a herd (certain seals); polygynous permanent mateship within a herd (baboons).

Among monogamous or polygynous animals the mating bond is more or less strictly kept; there are in this respect specific as well as individual variations. Monogamy is strictly kept among cranes, swans and geese. Among other species of birds the mates are occasionally unfaithful; we speak then of accessory promiscuity. A clear distinction may be observed between the two forms of promiscuity: promiscuity as the general rule which involves no organization of mateship; and accessory promiscuity which accompanies mateship. The latter is, as we know, no uncommon occurrence among men; on the other hand promiscuity as the rule has never under searching investigation been known among any contemporaneous or historic peoples. Among birds and mammals, notwithstanding the many species in which mateship is the rule, there are a few in which mateship is just as regularly absent, and with these latter promiscuity is the rule. Here are to be mentioned ruffs, North American cowbirds, European cuckoos, bats, North American bison, hares, quails, argus eyed pheasants. Among the black cocks and the capercaillies the sex relations border on promiscuity.

Out of mateship, on the appearance of offspring, there arises the family, whenever the animals concerned remain together for a time. This union is brought about through the family instinct. According to whether both parents or only one parent stays with the young, or whether the young remain united by themselves for a while, we may distinguish four categories of the family: parent family (certain beetles and fishes, many birds and mammals); father family (some fishes and frogs); mother family (some insects and spiders, some fishes, frogs, birds and mammals); child family (some caterpillars and fishes).

Mateship and family among animals are both connected with breeding. The herd, on the other hand, is a form of society which, as such, has nothing to do with sex and reproduction. Mateships and families may, however, as we saw, be included within herds. The bond of the herd is the social instinct. Three distinct kinds may be noted. First, temporary herds are those which are bound together by a temporary manifestation of the social instinct (traveling swarms of locusts, dragon flies and other insects). Second, seasonal herds are those which

appear in species with a mating season. In this classification a further distinction should be made between herds during sexual inactivity and herds during the breeding period. Some species congregate in herds only during the annual periods of sexual inactivity, while during the breeding period monogamous (many migratory birds) or polygynous (the South American ostrich and Indian buffalo) mateships segregate themselves from their own kind. Other species, however, live in societies throughout the year, but the structure of the herd changes with the seasons; with the fur yielding seal, for instance, the herd consists during mating time of numerous harems belonging to individual males, while the old males and the youngsters not allowed to mate by the masters of the harems remain aloof. During sexual inactivity, on the other hand, the males and females live in separate herds—the female herd including the infants and occasionally also the young males. The third distinctive type consists of permanent herds which may be formed either by seasonal mating (e.g. rodents living in settlements) or by continuously mating species (e.g. gorillas). Every such herd consists on close analysis of a number of monogamous (rodents and gorillas) or polygynous mateships (baboons), with their respective young. A special kind of permanent herd is constituted by the “states” of the social insects.

To investigate and to classify the various forms of animal societies thus enumerated is the task of special animal sociology. There is, besides, general animal sociology. The latter studies those general features which appear whenever any association is formed, such as the establishment of a social scale, mutual understanding, mutual assistance, etc. It ascertains, for instance, that many birds and mammals, through struggle or intimidation, immediately establish a system of rank in their societies; it studies leadership in societies, mutual help and attack, common games, dances and signal callings, communication and imitation, teaching and tradition within animal societies, property of the individual and of the entire society, manifestations of the collective psyche, etc.

Animal sociology is not without importance for human sociology. In a certain sense it forms its foundation, for much that appears “typically human” in an isolated consideration of man becomes in the light of animal sociology purely a phenomenon of group psychology. With animals it is primarily internal ties and in-

hibitions that regulate their cohabitation in mateships, families and herds. The supreme regulatory principle is not brute force; that intervenes only where irreconcilable opposites collide. In no sense is everything in confusion in animal herds, either in sexual or in other affairs. Let us consider, for example, a brooding swarm of doves. These animals live monogamously, yet there exists accessory promiscuity inasmuch as infidelity occasionally occurs among the mates. It would be entirely erroneous to attempt to explain the union of monogamously paired doves only by the general absence of opportunities for unfaithfulness. The objection to this is that no social organization, even if it be that of brooding doves, can be based on such external factors. As an important condition we must always have the deeply entrenched predisposition of single individuals to bring their instinctive reactions to bear upon an objective situation no matter what obstacles stand in their way. There is, besides, a variety of supplementary supporting factors such as respect for the strength of the beaks of the other mated doves, claims made by the necessities of nest building, bringing up the young, etc. The primary fact, however, is the instinct of monogamous mateship.

It has repeatedly been asked which is older, mateship and the family or the herd (in the case of primitive man, the horde), and whether perhaps one may have grown out of the other. Animal sociology teaches that the question is not well put; for mateship and the family, on the one hand, and the herd, on the other, are forms of society formation which in certain animal species exclude one another, in others exist side by side. The mateship and family, on the one hand, and the herd, on the other, are based on different biological principles, of which neither is traceable to the other.

Mateship, family and herd (horde) are pre-human biological institutions; when, as we have to suppose, in the evolution of man human reason gradually became differentiated from instinct, it found all these social forms pre-existent, and nothing remained but to justify them after the fact by rationalistic considerations.

Consult: Alverdes, Friedrich, *Tiersozologie* (Leipzig 1925), tr. by K. C. Creasy as *Social Life in the Animal World* (New York 1927).

ANIMISM, the belief in spiritual beings, is one of the oldest inventions of man. We must infer that it dates from palaeolithic times, and its subsequent world wide distribution and incomparable influence upon human thought and activity are to be paralleled, for instance, in the invention of fire. Both are so fundamental in human history that no one has successfully imagined an order of human events in which they do not figure.

This universally animistic state of mind of primitive peoples was, to the early anthropologists, exponents of nineteenth century English rationalism, bewildering and very nearly incredible. Since it was their habit of mind to assume the rationality of human processes, Tylor and Spencer were quite naturally overwhelmed by this unanimous fantasy: the ascription of being, on the pattern of that known in human beings, to the external world. Their difficulty was intelligible enough. Animism is not, like forms of marriage, to be understood ultimately in relation to the biological structure of man or, like the forms of industry, to his needs of food and shelter. Even where animistic practises were used in connection with economic pursuits, they were, from the rationalist's point of view, supernumerary; that is, man knew the technique of stupefying fish in a pond or of burning over the ground before seeding, and the animistic acts and tabus that were inevitably superadded, if not to agriculture, then to hunting or to warfare, could not be justified on the economic basis.

Tylor derived animism from those experiences which gave man the notion of the separable human soul. These are primarily dreams, but also include shadows, reflections in the water, etc. Once primitive man had arrived at the hypothesis of his own soul, he transferred the notion first to other humans and later to the inanimate world. Spirits, then, however many, are rooted in one common notion. Those which are transferred to the world of the dead gain currency as ghosts; those which are transferred to animals, as animal spirits; those which are transferred to the world of nature, as all the host of nature spirits. There are also those "souls" of disease and nightmare against which so much ritual is directed, and those guardian "souls" which as the personal protectors of individuals are so variously known.

Tylor emphasizes the fact that spirits are not necessarily differentiated from the objective world on the basis of their spiritual, i.e. non-

material character. Spirits are supposed to leave footprints, to need holes cut in partitions through which it is desired that they should pass, to dwell together in villages often as material as those of human beings.

Spencer in his discussion of animism laid weight also on the importance of the concept of the human double. Andrew Lang stressed the fact of trance and psychic experience as calling into being animistic conceptions. More recently Marett has given theoretic prominence to the occurrence of non-personalized concepts of spirit. These are well known under the Indian names of *orenda* and *manitou*, and better yet the Polynesian term of *mana*. Marett calls this aspect "animatism," and describes it as a simpler form of the religious concept than that of the visualized supernatural beings with whom Tylor was specifically concerned. J. W. Hauer, agreeing more nearly with Lang's emphasis, has recently derived animism from the religious experience, the intrusion of compelling psychic states felt to be authoritative and imposing upon mankind the animistic interpretation.

Tylor's exposition of animism has been challenged by a number of anthropologists, notably Durkheim and Lévy-Bruhl, on account of its over-intellectualist character. While both of these critics phrase their problem in such a way that they do not contribute specifically to a discussion of animism, their criticism of the classic statement of animism is in line with modern psychological thought.

In common with other thinkers of his time, Tylor was interested in the origin not of complex emotional backgrounds but of conceptual phenomena, and he regarded these as of primary importance in behavior. It is more in accord with present day conclusions to regard the concept as secondary and the act as primary, and it is natural that the modern problem in regard to animism should have shifted. In Marett's phrase, we think of religion as "danced out, not thought out," and this shift is especially significant in connection with the problem of animism. The question has been distorted by the classical emphasis. It has been regarded as a department almost of cosmology, as an affair of theories and beliefs. In the modern view it is animistic behavior that is crucial: that behavior which plays opposite to the external universe regarded not as thing but as person. Our present day dichotomy of behavior has isolated two distinct types: the type directed toward things, which follows

strictly a cause and effect sequence; and the type directed toward persons, which runs the gamut from love to manipulation, but which deals only in small degree with measurable cause and effect. Of this dichotomy primitive man knew little. As we have noted above, he knew thing-techniques, but he did not regard them as ruling out person-techniques. He harangued the tree as bride or as child, taking it to wife with the ordinary marriage rites, or cradling it according to the ceremonial of childbirth, at the same time and place that he demonstrated his mastery of felling large trees without the use of iron. He simply made no dichotomy where with us it has become fundamental.

Behavior of this sort in our own civilization is most easily observed in the child. Modern child psychology exhibits many examples of the child's assumption that his relations to the inanimate world are of one pattern with those toward the animate world of people: he fondles as he would his mother the pretty thing that has pleased him, he strikes the door that has slammed upon him. Animism considered as behavior is nothing more than this; properly speaking, it is only the expression of a state of mind that has not made our distinction between behavior toward persons and behavior toward things, but which brings the whole field under the one rubric, treating the entire external world according to the pattern learned in dealings with fellow beings.

From this point of view animism loses much of its fantastic character. It is not evolved *de novo*, but represents a well tested gamut of acts and accompanying emotions, from adoration and cajoling to bargaining and legalistic compulsion, all of which are familiar in the sphere of human relations and are here simply transferred to the supernatural. If primitive man believed that his most serious matter of fact efforts in hunting or agriculture were still insufficient, without the addition of prayer and fasting, to propitiate the supernatural beings, it was no more than we ourselves feel necessary in such human situations as that of parents and children. We judge material care still insufficient unless we give evidence also of a certain emotional attitude. In other words, the religious behavior of primitive people followed rules of conduct which we have not ourselves repudiated; the difference lies in their belief that that part of the external world which we now manipulate by knowledge of cause and effect sequences

should be managed by the same rules as those that obtain in the human world.

This view of animism shows clearly that it does not bar out, even for the most primitive, the development of naturalistic control of the environment. We have used the example of the felling of trees. Any field of activity illustrates the same point. The Australian or the Bushman by minute knowledge of a locality can obtain water from roots and water holes unavailable to a civilized person; a Polynesian can build a trustworthy boat from materials that would seem unusable to others. In addition they use incantations, fastings and tabus. It is obvious that the roots of modern science are in the matter of fact techniques and knowledge of the environment, not in the magico-religious realm at all. Frazer's contention that magic is a primitive science is untenable. At any period in the world's history, in so far as any procedure depended on supernaturalism it was removed from scientific method.

It is important to observe that animistic behavior was fallacious only in that it was applied outside the realm of man's dealings with his fellows. With the person-technique as such, as a technique that must always be in some measure removed from cause and effect considerations, we can have no quarrel. Human beings are most moved, not by mathematical demonstrations, but by love, by gifts, by cajolery, by punishment. Our cultural emphasis tends to slight this fact, stressing in practical affairs the possibility of impersonal manipulation of groups, and in psychological thought the cause and effect sequences in the individual. We may well remember that we often fail by our methods when primitive man would succeed by his. A labor dispute attacked by the techniques used in the rain ceremonials of the Pueblos of the Southwest would never need the militia. Within the field in which this type of behavior was perfected—in the field of personal relations—the person-technique of primitive people is often admirable. And if their thought characteristically extends beyond reason the confines of this type of behavior, it is at least arguable that ours extends as far, in the incalculable region of human relations, the confines of the thing-technique. The fact that European civilization has made its most significant contribution in exploring mechanical causation should not blind us to the fact that those other forms of behavior which are characteristic of human relations were carried

to a high point of art by many peoples in their varieties of animistic behavior.

ANNAPOLIS CONVENTION. *See* CONSTITUTIONAL CONVENTIONS.

ANNENSKY, NIKOLAY FIODOROVICH (1843-1912), Russian statistician, journalist and political figure. After studying law and history in preparation for an academic career he joined the statistical department of the Ministry of Transportation. This official connection was severed in 1880 when, because of his outspoken liberalism, he was exiled by police orders to Siberia for a term of three years. On his return to European Russia he managed the statistical department of the Kazan, and later that of the Nizhni Novgorod provincial *zemstvo*. During his association with the latter it acquired the reputation of an all Russian school for *zemstvo* statisticians. In his farm assessments Annensky relied largely upon the results of soil tests, a procedure which later gained wide acceptance in Russia. In 1895 he moved to St. Petersburg to become chief of the municipal statistical bureau and to join, with Korolenko, the editorial staff of *Russkoe Bogatstvo* (Russian Fortune), the leading monthly organ of populist socialism. Beginning in 1882, when Annensky attracted considerable attention by an article on the "New Trends in Economics" in which he criticized German socialism of the chair, he contributed articles on political and economic subjects to various periodical publications. After 1900 he devoted himself entirely to journalism, and in 1904, upon the death of Mikhaylovsky, the editor-in-chief, became the chairman of the editorial board of the *Russkoe Bogatstvo*. In his articles for this magazine Annensky dealt with social and economic topics, such as budgetary problems and questions of financial policy. His attention, however,

was absorbed mostly in editorial work in the economic and political sections of this publication. He helped to found the Laborite People-Socialist party in 1906 and was elected chairman of its central committee, an office which he retained to the day of his death.

V. MIKOTIN

ANNEXATION is primarily a term of international law denoting the act of a state, within the limits of that law, in adding to the territory held under its sovereignty territory not so held prior to that action. It confers all powers of use, exclusion and alienation. The term cannot in strict accuracy be applied to extension of the authority of the state over territory which even after such action remains outside the scope of its full sovereignty, as in the establishment of a protectorate, military occupation, acceptance of a League mandate or the acquisition of territory on lease. The action must be taken for the state by public officials or persons previously authorized so to act or whose action is subsequently ratified by the state. There is no etymological reason why the term should not be applied to acquisitions of territory not previously held by another state, but it is more frequently applied to acquisitions of territory previously so held.

The only ground upon which annexation may validly be based, in international law, is that of consent by the state whose territory is annexed in whole or in part (*see* **CESSION**) or, in the case of territory not formerly held by another state, consent by the international community to the act of the annexing state. The consent of the predecessor state, in the former case, may be given tacitly (as in peace time prescription), and even under coercion, as by cessation of resistance to conquest (operation of rule of *uti possidetis* at end of war); but without such acquiescence no proclamation of annexation or military conquest by a second state is effective (Belgium, 1914-18). No plebiscite of the inhabitants of annexed territory is as yet necessary under international law to confirm either the action of their former government in making the cession or the action of the new sovereignty in making the annexation. On the other hand the consent of the ceding state may be given expressly, in a treaty agreement for sale, exchange, etc. In either case recognition of the fact of transfer is incumbent upon all other states, in view of the standing rules of international law permitting acquisition of title by these

means, in the absence of prior agreements by which the cession is placed outside the power of the ceding state (Platt Amendment), or of subsequent agreement of the parties reversing the cession (Port Arthur). Outside states may not, however, by agreement among themselves transfer the territory of another state without its consent (Bessarabia), although in recent years several cases of international action to create or sanction title to territory for an individual state have appeared (Danzig). Finally, in the case of territory not previously held by another state the agreement of the international community is admitted in the standing rules of international law authorizing acquisition of territory by discovery, occupation and accretion. Subsequent recognition of actual annexations of all types will operate to confirm title, but in no case does it appear that notice of annexation need be given or such recognition obtained until the question arises in the routine course of international relations. In spite of many opinions expressed to the contrary, it does not appear that actual occupation by the authorities of the annexing state is required to complete annexation where the basis of annexation itself does not require such occupation; thus such occupation is necessary to acquisition by conquest, occupation of new lands, prescription and accretion, but not necessarily to acquisitions by discovery.

The result of annexation is to transfer the allegiance of the inhabitants to the new sovereignty; nationals of the old sovereignty become nationals of the new, and resident aliens transfer their allegiance as such to the new state also. The latter may permit the inhabitants—nationals of the former sovereignty—to retain their nationality on any terms which it may think desirable (e.g. removal); it is under no obligation to do so. The existing public law, including criminal law, remains in force except where incompatible with the public law of the annexing state, as do the local governmental organization and practise, subject to the same limitation: thus in certain cases annexed units may retain a great deal of their identity, as before the annexation (Texas). Any military government set up by the annexing state during military occupation similarly remains in effect. *Titles to public property rights* pass to the new sovereignty; public obligations are inherited by it only where they have been reasonably incurred for the betterment of the territory annexed, but in no case are obligations contracted for resistance

as the annexation so inherited. In view of the many variable and indefinite factors which go to determine the results in this situation, it is held that the annexing state may decide for itself, if the matter is not regulated by the agreement for cession, what obligations it will assume as a result of annexation, subject to these general principles. Treaty obligations of the annexed territory are inherited by the succession state, where the annexed unit does not retain power of discharging such obligations itself, subject to similar principles. The law of private relations, and private rights and obligations thereunder, remain unaltered, subject to the authority of the new sovereignty.

Historically annexation has been extremely important in the relations among the European nations and in the development of the United States. The former have not only in past centuries annexed vast colonial territories in the Americas, in Africa and Asia (relatively uncommon application of the term), but have also from time to time annexed from one another metropolitan territories in Europe itself (Alsace-Lorraine, Poland), usually as a result of conquest. The United States annexed vast territories on the continent of North America and, later, overseas, mainly as a result of purchase, with some admixture of conquest. The acquisition of original title by discovery and occupation of new land being now no longer of great importance, it seems probable that annexation as a basis of national territorial sovereignty will grow in importance in the future. But the decreasing discretion of the nation in controlling use of its own territory, as a result of increased international supervision (internationalization, mandates, minority protection, etc.), together with the growing tendency to restrict freedom of annexation ("no annexations," Article 10 of the Covenant, demand for plebiscites) may counterbalance this influence. Any arrangements for revision of the territorial status quo by international agreement, implicit in the outlawry of conquest, would further emphasize this change. Moreover there seems to be some decline in the eagerness of states to make annexations of territories, continental or colonial, populated by hostile peoples or by backward races requiring expensive tutelage by the administering state. The future of annexation as a form of state action is problematical.

ANNUITIES are yearly or other periodic payments of a certain sum of money granted to one for life, years or in fee, chargeable upon the person of the grantor (Sir Edward Coke, *circa* 1615, *et al*). The annuity is often confused with a rent charge, which is a charge against lands in the hands of the purchaser and arises out of the land itself. It should not be confused with gifts of incomes from funds, with incomes or profits indeterminate in amount, or with incomes from ordinary legacies, however payable. The periodic payment of sums certain, chargeable upon rights and personal property, seems to have become obsolete.

Annuities may provide sums certain either for others or for oneself. The first type of annuity is the older. It is of testamentary character and takes the place of a legacy in the lump. In modern times this form of annuity is used in connection with marital separation agreements and as provision for wayward or spendthrift children. Provision for self, or jointly for self and spouse, seems to be the prevailing practise.

The annuity may have been in vogue in ancient India, China, Babylon and Assyria. Annuities were granted in Egypt at the close of the twentieth dynasty (Setnakht). The Romans bought and sold annuities. Early in the Middle Ages in England and in northern Europe annuities chargeable against the person of the grantor evolved from payments charged against lands, rights, tolls and personal property. From the eleventh to the fifteenth centuries the expense of petty wars in Italy, Germany, England, Flanders, Brabant and elsewhere was met by loans repayable as annuities chargeable against the credit of the cities and countries involved. Loans for the general purposes of

cities, repayable as annuities, for life or years (singly or jointly), or in perpetuity, were often resorted to (Tournai, Bruges, Nuremberg, Florence, Ghent).

The "tontine," a pseudo-annuity, arose toward the end of the seventeenth century as a result of the attempt of Mazarin and Colbert to resuscitate French finances. Lorenzo Tonti, the inventor of this plan, proposed that a fund of 25,000,000 livres be collected and each year interest be paid thereon at a lower rate to younger members and a higher rate to older entrants into the fund. Subscribers were to be divided into ten age classes, each constituting a closed group, surviving members of each class receiving annually a pro rata share of the interest fund allotted to the class. After the death of the last subscriber the original fund reverted to the state. Tontine loans were also issued in Amsterdam (1671), Groningen (1671) and in other places on the continent. Tontine practises survived into the eighteenth century.

The calculation of annuities passed from a guesswork basis to one based upon observations of human mortality in the seventeenth century, chiefly as the result of the work of Jan de Witt, who in 1671 presented his famous report to the Parliament of Holland and West Friesland. This report contained the table of minimum values to be accepted in return for life annuities, the principal sums to be used in financing the wars which threatened Holland at that time.

The English government attempted for the first time in 1692 to raise money through life annuities. The granting of life, deferred and term annuities in England supplemented the earlier instruments of tallies, navy and exchequer bills. During the eighteenth and nineteenth centuries annuities accompanied the state lotteries, lottery loans, the issue of consolidated 3 percent stock, the victualing bills, tariffs and other sources of the king's revenue. Annuities have been employed in American finance only once—by Hamilton in the funding of the revolutionary debt.

The common or formal types of annuities now in vogue may be divided into two main classes: annuities certain and contingent annuities. An annuity certain is a series of payments made at equal intervals over a fixed period of years. The contingent annuity is one for which the date, either of the first or last payment, depends upon the happening of some event, the time of whose occurrence cannot be foretold.

Annuities certain may have the first payment

at the end of the first period (immediate annuities); at the beginning of the first period (annuities due); or the first payment may be made after the lapse of a given number of years (deferred annuities). When annuity payments continue forever they are said to be perpetuities.

The simplest form of contingent annuity is the whole life annuity, i.e. payments are made throughout the life of an individual. Life annuities are often granted jointly to several lives, or as long as one, at least, of several lives survives. An annuity is said to be forborne when the payments are not taken when they fall due but are left to accumulate at compound interest.

In annuity calculations it is necessary to approximate from tables of the probability of human survival and of compound interest the present value of the series of payments. When the payments are made at equal intervals and in equal amounts for a stated number of years, (n), the present value (a_n) and the amount when forborne (s_n) may be expressed as sums of geometric series, that is:

$$a_n = v + v^2 + v^3 + \dots + v^n$$

$$a_n = \frac{1 - v^n}{i} = \frac{1 - (1 + i)^{-n}}{i}$$

and:

$$s_n = 1 + (1 + i) + (1 + i)^2 + \dots$$

$$+ (1 + i)^{n-2} + (1 + i)^{n-1}$$

$$s_n = \frac{(1 + i)^n - 1}{i}$$

To introduce the life contingency element in the simplest manner it is necessary to take into account, with the present value of each payment, the probability that the annuitant, or receiver of the payments, will survive a given number of years (n). That is:

$${}_n a_x + v p_x + v^2 {}_2 p_x + v^3 {}_3 p_x + \dots + v^n {}_n p_x$$

where $v = (1 + i)^{-1}$ and ${}_n p_x$ probability of a person aged x surviving n years. The commutation columns (invention of John Nicholas Tetens, 1786) of the life table chosen for the given class of annuitants may be used to sum such series. The mathematics of the annuity has engaged the attention of the ablest of minds—De Moivre, Dodson, Simpson, Price, Euler, Tetens and others.

In modern practise one finds the annuity form expressed in retirement and disability

pensions, in the "income" or "instalment" settlement features of ordinary life insurance, in the disability annuity annexes of life insurance and in the wide variety of annuity contracts *per se* offered by insurance institutions. In recent years the sales of annuity contracts have increased remarkably. Since 1916 the companies reporting to the New York Insurance Department show an increase of 160 percent in sums received and of 120 percent in the reserves set aside for annuity payments. The total reserve fund so held by these companies in 1926 was approximately a quarter billion of dollars.

Insurance students feel that with the prospect of an increase in the purchasing value of money and a decrease in the yield on fixed-rate securities available to the private investor, moneyed persons in the United States will be attracted more and more to the certain proceeds of an annuity. The wage working population also may benefit in the future from the increased sales of the retirement and disability annuities now available on the "group" plan. Under this plan the consideration for the annuity is paid for jointly by employer and employee. These annuities are sometimes combined, in one arrangement, with group policies for life, health and accident.

Deferred annuities for persons not covered by industrial or establishment pension systems seem to meet with particular favor at the present time. These are paid for by the prospective annuitant in lump sum early in life, or in instalments during the working period of life or through a combination of these two methods. The first payment to the annuitant usually begins at age 60 or 65. If the annuitant dies before the annuity payments begin, the return, without interest, of the amounts paid in can be arranged ("refunding" or "guaranteed minimum return" contracts).

(London 1871-80) vol. i, 98-168; Institute of Actuaries, London, *Textbook of the Principles of Interest, Life Annuities and Assurances*, 2 vols. (London 1901-02) vol. i; Avery, John M., "The Nature of an Annuity" in *Association of Life Insurance Counsel, Papers* (1928) 65-81; Kopf, Edwin W., "Early History of the Annuity" in *Casualty Actuarial Society, Proceedings*, vol. xiii (1926-27) 225-66.

ANSELM (c. 1033-1109), theologian and philosopher. In 1093 he was chosen archbishop of Canterbury, and a quarrel ensued with William Rufus concerning investitures and homage. This seemed to Anselm to involve the fundamental question of the liberty of the church and resulted in a trip to Rome in 1097. There he took a prominent part in the Council of Bari (1098) and the Synod of Rome (1099), where the decrees against simony, concubinage of clerics and lay investiture were renewed. After the death of William Rufus he returned to England and after some difficulties reached an amicable agreement with the new king, Henry I. The terms are not definitely known but it appears from contemporary documents that Henry gave up his claim to the investiture of bishops and agreed to abstain from arbitrary interference in their election. The pope, however, seems to have agreed temporarily that bishops should pay homage to the king.

Aside from his important role in the investiture controversy, Anselm was a towering figure in scholastic thought. His writings comprise, in addition to philosophical and pedagogical works (*De veritate*; *De grammatico*), a discussion of all the theological themes which agitated his time—the freedom of the will, the humanity of Christ, the sacraments, the Holy Ghost and the fall of the devil. On the crucial question of the existence of God, Anselm's ontological proof is classic. The collected works of Anselm appear in J. P. Migne's *Patrologia latina* (vols. clviii-clix, Paris 1863-65), which contains also Eadmer's *Vita S. Anselmi* (vol. clviii, cols. 49-134).

RICHARD MCKEON

Consult: "Anselm von Canterbury als Vorkämpfer für die kirchliche Freiheit des elften Jahrhunderts" in *Historisch-Politische Blätter für das katholische Deutschland*, vol. xlii (1858) 535-61, 606-27; Church, R. W., *Saint Anselm* (London 1873); Rule, M., *Life and Times of Saint Anselm*, 2 vols. (London 1883).

ANSON, WILLIAM REYNELL, BART. (1843-1914), English law teacher and educational leader. In 1874 he became Vinerian reader in English law at Oxford; in 1881 he was elected warden of All Souls, and became vice chancellor of the university in 1898. He was active in the revival of the study of law at Oxford, and his work there resulted in a succession of important law textbooks for students and in the establishment in 1884 of the *Law Quarterly Review*. Anson's writings are characteristically

those of a teacher. His *Principles of the English Law of Contract* (Oxford 1879, 16th English ed. Oxford 1923; 8th American ed. Chicago 1929) was a model introduction to the subject in the last century, when the chief reliance was on texts rather than on the original authorities. It represents the nineteenth century movement for organization and systematization of the common law by an analytical-historical method, in which it was sought to put English law into the mold which the German historical jurists had constructed as an instrument of university teaching. *The Law and Custom of the Constitution* (3 vols., Oxford 1886-98; 5th ed. Oxford 1922) is an analytical survey of "the machinery of the existing Constitution of England," seeking to take it to pieces by analysis and to explain the nature and working of each part.

In education he had much to do with the constitution of All Souls as finally determined by the reforms after 1877; he was active in support of the Education Bill of 1902, which sought to incorporate the voluntary schools with the board schools in a single national system; and he helped to lay the foundations of the organization of education which has obtained in England since 1918.

From 1899 to 1914 he was burgess (member of Parliament) for the University of Oxford, and was parliamentary secretary of the education department from 1902 to 1905. He was of the best type of nineteenth century liberal, inclined to improvement but cautious, tolerant, appreciative of all sides and skilful in compromise.

ROSCOE POUND

Consult: Henson, Herbert Hensley, *A Memoir of the Right Honourable Sir William Anson* (Oxford 1920).

ANTEQUERA, JOSÉ MARÍA (died 1891), Spanish writer on juridical and historical subjects. Antequera served for many years in the ministry of "Gracia y Justicia," was editor of *El faro nacional* (1851) and of *El estado* (1859), and contributed to various periodicals, among them *El cristianismo* and *La ilustración católica*. His best known work is *Historia de la legislación española desde los tiempos más remotos hasta nuestros días* (Madrid 1849, 4th ed. 1895), the fruit of twenty-five years of study. He takes the view that law and legal institutions are an epitome of the religious, social and political ideas of a people, and hence stresses particularly those codes and institutions which reflect the internal growth of the Spanish nation. While much in this book has

been superseded by later monographs in special fields, particularly in regard to the origins of the *municipios*, the *Fuero Juzgo*, the *señorios* and the Aragonese and Catalan primitive codes, it still remains a valuable survey of the field and will serve the student as a useful introduction and contrast to other works on the same subject. He gives a list of the most important *fueros* from 780 to 1523, and summaries of all the important codes and of the *fueros* which came to serve as models. He wrote also *La cuestión religiosa en la historia legal de España* (Madrid 1870).

MARIE R. MADDEN

ANTHONY, SUSAN BROWNELL (1820-1906), American feminist and agitator for social reform. The Hicksite branch of the Society of Friends had in Susan B. Anthony the most indomitable woman exponent of its left wing social creeds. From a home which was a center of discussion and activities highly radical in their day a brother and a sister of Susan's also bore to the outer world a gospel of humanitarianism. Their Quaker father had dared to marry a Baptist, and he held heretical opinions on subjects other than marital. Nor was he afraid to have his children do likewise. Their mother was a daughter of the American Revolution of the first rank, for her own father had fought for national independence. Thus in an invigorating domestic atmosphere were stimulated the mind and temperament with which Susan Anthony attacked the issues of her time—temperance, slavery, trade unionism, feminism. But she was not solely home bred. From the age of seventeen to the age of thirty she was a teacher, getting a first hand contact with labor in its twofold aspect of social problems and sex status. Remaining celibate, every ounce of her nervous energy went into the causes she espoused and made her the "propulsive fire" of the woman movement which had been launched in 1848 under the leadership of Lucretia Mott and Elizabeth Cady Stanton.

Fiercely persecuted at the beginning of her public career, Susan Anthony was the most revered woman in America the year she died at the age of eighty-six. She had given the largest measure of devotion to the combined tasks—finally approved—of widening industrial, educational and professional opportunities for women, erecting the principle of equal pay for equal work, extending women's rights over property, arousing their sense of civic responsibility and securing forum privileges for its

expression, practising what she preached in the matter of economic independence and applying her equalitarian philosophy to the emancipation of a race as well as a sex. Although she did not live to see ratified the federal amendment granting woman suffrage, she had agitated for it incessantly for fifty-five years. She had poured a steady stream of articles into the press, pleaded from platforms across the continent, drafted resolutions, circulated petitions, raised funds for publications and assistants, met the requirements of a difficult and voluminous correspondence, argued before state legislative committees and the Congress at Washington, struggled with a weekly paper, helped in editing the documents of the movement, and from 1892 to 1900 she carried the responsibilities of president of a national organization of women. In all her work, however, her emphasis was on the vote as an instrument, not a goal.

ANTHROPOGEOGRAPHY. *See* HUMAN GEOGRAPHY.

ANTHROPOLOGY.

INTRODUCTORY. Anthropology deals with man as a social being. The races, languages and cultures found in different localities and following one another in the course of time are the material and contain the problems of anthropological study. The historical events that have led to modern conditions and the sources of the differentiated forms of social life, whether sprung from a common source or of multiple origin; the processes by which modifications of race, language and culture come about by the action of inner forces and by mutual influences; the interrelations between man and his environment and those between race, language and culture; the types of mental activity found in distinct cultures; the relations between individual and society—these present some of the problems that anthropology is trying to solve.

Its subject matter includes all the phenomena of the social life of man without limitation of time and space. From an anthropological viewpoint human life of the earliest times and of the

remotest parts of the world is no less important than that of historic times and of our own race. The geographical distribution of forms of human life and their historic sequence from earliest time to the present must be included in the scope of anthropological researches. The first task of the science is therefore the reconstruction of the history and distribution of mankind and of the forms of human life.

This material must be supplemented by the investigation of the physiological reactions of the body determined by heredity and environment; of the mental processes of the individual under the stresses of natural and social environment; and of the behavior of society. The analysis of static types, languages and cultures alone is insufficient for an understanding of their development. The dynamic conditions of change require a knowledge of the sequence of events and of the functioning of society and of its component individuals.

The life forms of any given people exhibit three distinct phenomena: bodily form, language and culture. Culture itself is not a unit, for the manifestations of social life are diverse in character. Bodily form is determined by biological conditions, by the influences of heredity, environment and selection. Language is largely dependent upon linguistic processes. Although these are intimately related to other cultural phenomena they are so unique in their character that the linguistic processes may be considered separately. Culture in the narrow sense of the term is highly complex, for the conditions under which economic life, inventions, social forms, art and religion develop are not analogous, although in many respects interrelated.

A reconstruction of the history of mankind must take into account all these aspects, for each one throws light upon a definite series of happenings. Since the conditions under which change takes place in bodily form, language and culture are quite distinct, it must not be expected that the same series of events will be reflected in each. Observation shows that these groups of phenomena possess only slight coherence. In modern times the bodily appearance, speech and culture of the American Negro show a continuance of racial type combined with complete change of language and culture. Earlier occurrences of the same type are illustrated by the substitution of Latin for Iberian in Spain and of Arab for Berber in North Africa. Sometimes languages persist notwithstanding changes in type due to the intermingling of races, as

among the Athapaskan Indians who live in isolated localities on the Mackenzie River, in California and on the Mexican border. Their languages are closely related, their types quite distinct. The differences of culture in Africa, combined with similarities of types and close relationship of languages, also illustrate the independence of cultural development from physical form and language.

On account of the disparity of these elements classifications of mankind based on bodily form, language and culture give contradictory results. Each group of phenomena must be looked at independently as reflecting one aspect of the history of mankind.

Two methods for the reconstruction of human history during those times in which no written records exist are available: prehistoric archaeology and the comparative study of similar phenomena in regard to form and distribution. Prehistoric archaeology can give us information only on the occurrence of such tangible objects as skeletal remains, objects of stone, pottery, bone; in favorable cases more perishable materials may be preserved. Fragments of intangible aspects of culture may sometimes be inferred from the forms of artifacts; but language, beliefs and customs are, on the whole, inaccessible to archaeological research. The possibilities of comparative study may be illustrated by the results of linguistic study, which has succeeded in establishing a considerable part of the linguistic history of the Indo-European family of languages.

The attempt to reconstruct the history of mankind is beset with one fundamental difficulty. Similarity of bodily form and culture is not always due to common origin but parallel forms may develop independently in distinct units. Independent parallelisms are found in life forms. The desert plants of Africa and America have a similar *habitus* and similar modifications of organs, although they are not genetically related. The marsupials of Australia have developed on lines similar to higher mammals, although they represent a distinct genetic line. Immediate physiological responses due to insufficient nutrition or to particular kinds of exercise are analogous in all races of man. In language similar categories, like a classification of concepts according to sex or form, or similar processes, like duplication of words or of parts of words for grammatical purposes, are found in a number of isolated regions. Similarities of inventions, customs and beliefs may also have

sprung up independently here and there. In language the number of words and grammatical forms, all of which are so many independent elements, is so large that in most cases historic relation can be definitely established by the existence of numerous independent analogous forms. It is frequently true that the question of the independent origin or historical connection of isolated cultural phenomena cannot be answered categorically. The occurrence of parallel phenomena in biological forms and in language does not countenance the assumption of the non-existence of independent origin of cultural achievements. For this reason we demand in a reconstruction of historic development that a proof of historical connection of cultural forms in distinct areas should be based on the occurrence of complex and unrelated phenomena and upon the distribution of the phenomena over continuous areas; also that the assumption of lost intermediate links should be used with greatest caution.

Consult: Ratzel, Friedrich, *Anthropogeographie*, 2 vols. (3rd ed. Stuttgart 1909-12), and *Völkerkunde*, 3 vols. (Leipzig 1885-88), tr. by A. J. Butler as *History of Mankind*, 3 vols. (London 1896-98), for the importance in historical reconstruction of a study of distribution over continuous geographical areas; this principle has been rigidly applied in the study of North American ethnology by Leslie Spier, "The Sun Dance of the Plains Indians" in *American Museum of Natural History, Anthropological Papers*, vol. xvi (1921) 451-527, and "Havasupai Ethnography" in *American Museum of Natural History, Anthropological Papers*, vol. xxix (1928) 81-392; Boas, F., "Tsimshian Mythology" in *Bureau of American Ethnology, 31st Annual Report, 1909-10* (Washington 1916) p. 29-1037; Kroeber, A. L., "Handbook of the Indians of California" in *Smithsonian Institution, Bureau of American Ethnology, Bulletin 78* (Washington 1925). Fritz Graebner, *Methode der Ethnologie* (Heidelberg 1911) takes the viewpoint that independent origin is impossible and assumes that a few correspondences in remote areas are proof of historic connection; on this basis he establishes *Kulturkreise* based on similarities which he assumes to be retained since remote antiquity. This theory has been adapted and expanded by W. Schmidt and W. Koppers, "Gesellschaft und Wirtschaft der Völker" in Obermaier, H., and others, *Der Mensch aller Zeiten*, 3 vols. (Berlin 1912-24) vol. iii, pt. i. Quite unacceptable are the views of G. Elliot Smith and his followers, who would derive all phases of human culture from Egypt (see, for instance, Perry, W. J., *The Children of the Sun*, London 1923). The other extreme is represented by Daniel Brinton who would not admit any borrowing. On the whole the earlier anthropologists, like Adolf Bastian, did not take a definite position on this question. Bastian was rather indifferent to the problem of historical transmission or independent development, because he laid stress upon the psychological conditions that bring into

being certain ideas everywhere; no matter whether the impetus may come from inside or outside, the same ideas will always develop. Edward B. Tylor, although primarily interested in the problem of the general line of evolution of culture, recognized the importance of the problem of independent origin versus historic transmission.

BIOLOGICAL ASPECTS. Man is closely related to the anthropoid apes, and the home of man must be looked for in an area in which early anthropoid forms occur. These are absent in America, present in southern Europe, Asia and Africa. The origin of man must, therefore, be looked for in the Old World. The oldest human remains belong to the early quaternary and are represented by a lower jaw found near Heidelberg. The form of the jaw is so distinct from later and recent forms that it has been described as a separate species, "*Homo Heidelbergensis*." In the middle quaternary another primitive type is found, "*Homo Neandertalensis*," remains of which occur in western Europe. It was probably not the ancestor of modern races, but a side branch. Towards the later quaternary, forms appear which are related to modern man. It is even possible that at this time the differentiation of the Negro race and of the Mongoloid races had occurred. The absolute time elapsed since the end of the quaternary is estimated at about ten thousand years. There is much difference of opinion in regard to the time when the Neanderthal man lived, but it can hardly be less than fifty thousand years ago. Crude implements made of stone are much older. Neanderthal man also possessed fire, and there are evidences, at the end of the period in which he lived, of fireplaces and burials. All this has a bearing upon race development, because the use of utensils and of fire characterizes the mode of life of man as that of a domesticated being, enjoying artificial protection and artificially modified feeding. The body of modern man shows clear evidence of the effect of domestication, for the hair form of the Negro, the loss of body hair, the length of hair on head and face, the blondness and general loss of pigment, the blackness of the Negro, the lack of periodicity of sexual function, the permanence of the female breast, the reduction in size of the face, are analogous to features that develop in domesticated animals. The history of human races must be considered from the point of view of the origin of races of domesticated animals. On the basis of morphological evidence it seems that two, perhaps three, fundamental races must be distinguished: the Negro,

which is found in Africa and in isolated places in southern Asia and the islands north and east of Australia, in general around the Indian Ocean; the Mongoloid in Asia and America; and as a third ancient type the Australoid and a similar type in southern India. The European would seem to be an early offshoot of the Mongoloid, while the Negro may be an offshoot of the Australoid.

At the present time a large number of local types exist, the history of which is difficult to trace. There must have been many centers in which during an early period of isolation distinct types developed, but this period has been followed by intermingling of distinct types, so that at the present time no sharp lines can be drawn between the varieties of man.

The individuals composing any local variety exhibit considerable differences among themselves. The brothers and sisters composing a single family—a fraternity—also show considerable differences among themselves. Each fraternity represents on the average a certain hereditary type, and when these types are compared they also exhibit a considerable variety of forms. When comparing neighboring groups, similar groups of fraternities are found in all. For this reason it is impossible to define a local race in such a way that the description would fit all members. All that can be done is to determine the frequency distribution of the various component types.

On account of these conditions it has been found necessary to give for each type exact measurements in place of general verbal descriptions. The selection of features that are commonly measured is determined partly by striking differences in form, as in the relations between transversal width and antero-posterior length of the head, partly by the ease with which exact measurements can be taken. Not enough attention has been paid to the morphological significance of the measurements selected. This would require a detailed inquiry into their permanence under varying conditions. The object of the metrical description is essentially a statement of the distribution of hereditary types and of their modifications by the environment.

It is not permissible to assume that individuals of the same bodily form, but members of distinct local groups, are genetically identical, for the series of their offspring will always revert toward the population to which they belong. If these are distinct, the offspring of each will develop on different lines. Too little is known of

the ancient development of types under conditions of isolation, of the effect of intermingling, and of the variability of types, to allow us to lay great weight upon the attempts to reconstruct the history of development of present types and to determine their ancient habitats.

The development of specialized types may be investigated in isolated, inbred communities. The high nobility of Europe and small, stable village communities offer such opportunities. It has been shown that under these conditions peculiar hereditary features appear with unusual frequency in the community. Up to the present time attention has been directed particularly to the occurrence of pathological traits, but observations on small tribes indicate that many normal traits may increase in frequency in the same way. The frequency of divisions of the occipital bone among the American Pueblo Indians, the hairiness of the Ainu, the excessively round heads in some of the valleys of the Alps must probably be explained in this manner. Minor differences of local types may perhaps all be due to the effects of early segregation of small groups, the characteristics of which were transmitted by heredity. In this case the range of variation of local types would be limited by the range of variation of the ancestral group. New features can develop only by mutations.

The question how far environment may bring about variation in type has hardly been investigated, because most metrically determined forms are assumed to be dependent on heredity alone. It is recognized that stature, an expression of bulk of the body, is strongly influenced by both heredity and environment, that the improvement of economic and hygienic conditions raises the average stature of a population through a direct influence upon the conditions of growth. Headform and facial width are also not absolutely permanent, but it is not known to what extent changes under varying conditions may develop. Their occurrence is analogous to skeletal changes that are observed in animals born in captivity which differ in details from the bodily forms of the parents.

Differentiation of local types may develop also by selection. If a relation exists between bodily form, on the one hand, and birth rate, mortality and tendency to migration, on the other, changes in the distribution of individuals will occur that are reflected in the impression given by the population as a whole, although physiologically determined changes in the individual may be entirely absent. It has been

suggested that a population containing many blonds exposed to a climate with intense sunlight would become darker by greater mortality of the blonds. Correlation between pathological processes and bodily forms is therefore of importance for an understanding of the development of local types. Much of our knowledge of this subject is vitiated by the difficulty of differentiating between social and organic conditions that determine the selective processes. In modern populations the different social strata do not represent identical types. This is due to the varying mobility of populations and local differences in social and economic status of the component parts. Since birth rate, mortality and migration are dependent upon social status, the distribution of bodily forms must undergo changes. It is doubtful how strong this influence may be in populations that are socially homogeneous. At the present time the identity and distribution of each local human type can be determined, but it is not possible to account satisfactorily for the processes of differentiation.

Wherever distinct types are in close geographical contact, and whenever archaeological research indicates a sudden change of type in a specific region, it is possible to trace by means of the study of types the migration of peoples. Thus the sudden appearance of round-headed types in prehistoric England is an indication of migration; the similarity of certain groups of Japanese to Malay forms proves the existence of racial relations; the contrast between the East Indian aborigines and the dominant people who resemble west Asiatics proves immigration of the latter from the west; the distribution of types in Italy proves the intermingling of the type of the Alps with the Mediterranean type.

A number of authors classify races according to certain combinations of metric and descriptive features, for instance, as tall, long-headed, narrow-faced, blond, and recognize another race as soon as any of the selected elements changes beyond a certain arbitrarily determined limit. Types thus isolated have no biological significance because it can be shown that almost all of them are unstable variants of one ancestral strain.

Paris 1926), tr. from the 1st ed. as *The Races of Man* (London 1900); Dixon, R. B., *The Racial History of Man* (New York 1923).

PSYCHOLOGICAL ASPECTS. The relations between bodily form and mental function are of particular importance for the student of human society, for if mental life is partly so determined, differences between the social life of various races may have to be explained on this basis. Much stress has been laid on this point. There is no doubt that individually the members of each local type differ among themselves no less in functional characteristics, both physiological and psychological, than in bodily build. Among different local groups, however, the same phenomenon is present that occurs in bodily build: analogous types are found in different local races. Furthermore function is much more subject to environmental influence than anatomical form. The same organism may be functionally adapted to a wide range of environmental conditions. For this reason organically different individuals are apt to react in similar ways when subjected to the same environment, while organically similar individuals will react differently when living in different types of environment. It is not correct to say that structure is entirely irrelevant in the determination of functional life, as extreme behaviorists claim; for we have ample evidence to show that organs, including the central nervous system, do not function in the same manner in all individuals.

These considerations are, however, irrelevant for the study of languages and cultural forms. The language spoken by a person, and his behavior, are not determined by anatomical forms and the functions depending upon them, but depend upon the social medium in which he lives. Identical twins, one of whom has grown up in Europe, the other in a culture analogous to that of Australian aborigines, will speak the

languages and be guided in their lives by the customary behavior of their environment. Differences in organically determined functioning may influence their position in this environment, but not the character of their behavior. Individual organic differences are immaterial for an understanding of types of culture.

Consult: Thurnwald, R., "Psychologie des primitiven Menschen" in *Handbuch der vergleichenden Psychologie*, ed. by G. Kafka, 3 vols. (Munich 1922) vol. i, pt. ii; Myers, C. S., and McDougall, W., "Physiology and Psychology" in *Cambridge Anthropological Expedition to Torres Strait, Reports*, 6 vols. (Cambridge, Eng. 1901-12) vol. ii.

LANGUAGE. While in most cases the study of bodily form results in rather vague impressions relating to the descent of populations, the study of languages often gives us more precise data in regard to historical events so far as they are reflected in language. On account of the independence of the numerous stems composing the vocabulary of a language the occurrence of the same stems in several languages is an incontestable proof of their historical relation. The stems undergo, in course of time, changes in form and in meaning. Definite directions of change in form prevail at certain times and in certain regions. These can be studied by a comparison of vocabularies, and it is possible to reconstruct older forms with a fair degree of certainty. By following out these changes in form and meaning of stems and of grammatical structure, the history of languages may be partially reconstructed. If related languages are found in extended areas we obtain proof of a historical connection and of a gradual differentiation, as in the cases of the Bantu Negroes who occupy a large portion of Africa and speak related languages, and of the Indo-Europeans who ranged before the period of modern colonial expansion from Spain and Ireland to India and Central Asia. When scattered remains of a language are found in a wide territory, as the Finnish on the Baltic, in Hungary and in isolated groups in Russia, significant inferences in regard to linguistic history may be drawn.

The importance of linguistics for anthropology is generally underrated. The categories of speech are the categories of thought, and the form of language directs the attention of the speaker in definite lines. Grammar embraces a set of categories that *must* be expressed by the speaker. In English I may say, "the man is sick"; in other words, "the definite single man at the present time is sick." The thought cannot be ex-

pressed without stating that we want to speak of a definite or indefinite man, of one or several, of past or present. Other languages select other aspects prescribed by their grammar. We may find the vaguest term, "man sick," or determinations quite different from ours that, however, must be expressed, such as "man (or men) near you visible evidently sick." A generalized translation from English into such a language is impossible. Language does not express the whole of a sense experience, but selects certain parts in regard to which the imagination of the hearer is restricted, while in regard to all others it remains free. The mental pictures produced by the statement of the same expression in different languages are not comparable in their details. In this way the flow of ideas depends upon the language spoken, for our thoughts may be directed in one way by a language that classifies objects according to sex, in other ways by those that classify according to social position or form, or by those that have no classification whatever. Our thoughts may be influenced by what is considered as an object, what as attribute; by what is regarded as a state and what as an action. In all these respects fundamental differences occur.

Similar observations may be made in regard to the vocabularies of different languages. The principles of the classification of experience differ considerably. Many American languages lay great stress upon form. To throw a long or a round or a flat object are distinct concepts. Actions relating to single or multiple objects may be differentiated. On the other hand, specific terms like our "to swim," "to fly," "to walk" may be expressed by a single stem, modified by qualifying elements. The combination of experience in categories follows the most diverse lines.

The influence of language upon cultural life must not be exaggerated, however, for a new cultural need is met by the development of new linguistic forms. The absence of abstract nouns, when it occurs, does not hinder the development of abstract ideas. If the need for them is felt by new experiences, language follows by giving a value to new, formerly unidiomatic expressions. The vocabulary of philosophy is largely of this character. Phenomena of nature that vary in form, each of which has a special significance in the life of a people, are differentiated in language. Thus the Eskimo differentiates between falling snow, drifting snow, snow on the ground, a snow drift and soft snow. We use only one term. The peasant

differentiates between horses according to age, sex and coat color; the Siberian native has numerous terms for his reindeer, the African for his cattle. Those not interested in horses, reindeer or cattle use only a very few terms.

Not all similar linguistic phenomena are due to historic connection. The fundamental traits of all languages show that their forms are a necessary result of the way in which we acquire experience. If every single experience were expressed by a single sound complex, i.e. a word, speaking and understanding would be impossible. It is necessary that the sounds should be recognized. This is possible only if the sounds are not too many and are fixed, and if the whole mass of experience is classified, so that similar experiences are grouped together and recognized by the symbol of the same sound complex. The classification of experience brings it about that the specific designation of an experience must be expressed by its subsumption under a number of classes which must be brought into relation. This means that words, i.e. classes, and grammar, i.e. devices of expressing relations, must be and are common to all languages.

Notwithstanding important differences, the sounds of most languages have in common the fact that they are produced by breathing out, or by the expulsion of air compressed in the oral cavity. Only the tribes of South Africa produce sound by sucking air into the oral cavity in which a partial vacuum is produced. Specific processes by means of which stems are grammatically modified are few: the addition of syllables as affixes (as in "un-kind-ly-ness"); changes of stem (as in "write, wrote"; "teeth, teethe") and significant position (as: "the wolf killed the man; the man killed the wolf") are universally distributed. Mechanical changes of sounds resultant from contact or other close association (as "impossible" for "in-possible") are frequent and of varied character. Sometimes historic changes of sound follow the same rules in widely separated areas. Thus the *k* in Bantu has changed in many dialects to *ch* (as in "church"). The same change occurs in a number of American languages. The effect of the loss of accent of a syllable has also often the same effect in regard to its phonetic development. Thus linguistic data give a safe proof of the independent origin of similar phenomena in remote parts of the world.

CULTURE. Culture embraces all the manifestations of social habits of a community, the reactions of the individual as affected by the habits of the group in which he lives, and the products of human activities as determined by these habits. On account of the heterogeneity of the habits of life it is customary to describe culture from a number of distinct viewpoints: the adjustment of man to surrounding nature; the mutual relations of individual members of a society; and the subjective behavior of man. The adjustment to nature includes the use of natural products for the purpose of nutrition and of obtaining shelter, as well as for less immediate purposes. The relations between individuals include sexual life and the forms of social conduct; the subjective behavior is manifested in art, religion, ethics and science. These various aspects of cultural life are interrelated and their complete separation in a systematic description gives a warped impression of the character of culture. Nevertheless a full description cannot be given without taking up each aspect of culture separately.

The definition of culture given here indicates that so far as the relations of members of a species to nature and to other members of the same species are concerned, phenomena analogous to those of human culture occur in animal society as well. As a matter of fact many of the characteristic human adjustments are found in the animal world. Insects, birds and mammals preserve food for unfavorable seasons; they build shelters, sometimes of very complex construction; they store up provisions; ants cultivate fungi; apes use sticks and stones as tools; they may even break off a stick to be used for a specific purpose. The social relations of animals are varied. There are hermits who meet the opposite sex only at the time of pairing; there are large societies like swarms of fish that welcome any number of their own species and may even admit members of other species; there are other more rigidly organized societies with recognized leaders; and among insects we find the organized states of bees and ants with an elaborate division of labor. Property rights are asserted by individuals and by animal societies.

It is even doubtful whether the culturally determined, purely subjective behavior is entirely absent among animals. The habits of the bower-bird suggest a pleasure in form. Apes seem to enjoy ornaments and rhythmic movements. Domesticated animals distinguish forbidden acts from those permitted. There is no absolute gap between many of the aspects of human culture and the life habits of animals.

In the relations of man to nature the procuring of food and shelter are fundamental. With the spread of man over all climates, ever new adjustments to the food supply and protection against the rigors of climate become necessary.

Food. Archaeological evidence proves that during the palaeolithic age, up to the end of the glacial period, man lived as a food-gatherer, that is, by hunting, fishing and gathering edible parts of plants, shellfish and other stationary or slow moving animals. These conditions still prevail among a few tribes, such as the Eskimo, the Indians of California and the western plateaus, the tribes of Tierra del Fuego, most of the Australians, the Bushmen and some other Pygmy tribes of Africa, the Veddah of Ceylon and the Andaman Islanders. Where the food supply is distributed irregularly through the seasons, the art of preserving food is indispensable. The Eskimo preserves little, partly because the supply of sea mammals is fairly regular, partly because the climate makes preservation difficult. The Australians lay by enough to allow large assemblies to live for weeks on stored provisions. Permanent association of man with plants and animals, that is, cultivation of plants and domestication of animals, does not begin until the neolithic period. It seems probable that the dog is the oldest domesticated animal. Its domestication is now universal, except in a few of the islands of the South Pacific. Domestication probably developed through a form of symbiosis, the dog following human camps and living in part on the refuse of human food. It is significant that all the most important domesticated animals are gregarious: cattle, sheep, goats, reindeer, buffalo, horses, ducks, chickens and geese. It is therefore probable that the relationship of man to gregarious animals was one of the conditions that led to domestication. It has been suggested that the

hunter who follows the same herd establishes a certain property right over it, and that he protects it against the attacks of wild animals; that in this manner gradually a permanent relation between man and the animal was established that led to domestication. If this is true, domesticated animals would have served first of all as a food supply. Their use for other purposes would be a much later development. The present distribution of the use of milk suggests that this discovery is also a late acquisition.

Many of the cultivated plants occur also in great masses. This is particularly true of the grains. Wheat and barley appear in Europe as the first cultivated plants. The property relation of man to an area in which such grains abound may still be observed among the Indians of the Great Lakes who gather wild rice; or among the seed-gathering Indians of the western plateaus. From the more or less permanent relation of man to an area bearing an abundance of the food-producing plant the art of cultivation may have developed. On Vancouver Island we may observe that spots producing roots of cinquefoil are cleared of stones and marked as property by being surrounded by walls of the pebbles that have been thrown away; along the north Pacific coast tribal property is established by burning over woods in order to produce a larger supply of berry-bearing bushes. The relation of man to fruit-bearing trees seems different from this, because in some cases a single tree produces as much nourishment as a large area on which gregarious plants grow. It is remarkable that many of the plants used and cultivated are not edible without special preparation, on account of their taste or because they contain poisonous substances. Examples are the cassava potato and acorns. Some have lost these qualities under cultivation.

All early agriculture was practised without the help of domesticated animals. It was analogous to our cultivation of plants in gardens. The invention of the plough and with it the use of draft animals for tilling fields is a late invention of the people of the northern half of the Old World.

Shelter. In earliest times man dwelt in natural shelters such as caves. The labor bestowed upon representations of animals in the caves indicates that his stay in the caves was continuous. The kind of shelter erected in the cave or outside is not known. Some people uti-

lize caves even now. Among modern tribes the simplest shelter is a windbreak erected of poles and filled in with branches. More complicated are double windbreaks that offer shelter from two sides and tents that are closed all around. In some regions shelter is sought in subterranean or semi-subterranean dwellings. While these structures serve a number of individuals as protection against climate and partly against attacks of wild animals, the individual is sheltered by clothing. In the arctic climate life without clothing would be impossible; but in more temperate zones the requirements of clothing are variable. The Fuegian in a tempestuous, wet and chilly environment and the Indian of Vancouver Island exist with very little clothing, while in some tropical regions, as in Uganda, the whole body is covered. Climate alone does not account for the kind of dress used.

Inventions. The specific methods of procuring food and shelter depend upon inventions. The earliest art of which we know is the shaping of brittle stone by means of flaking and chipping, for use in striking, breaking and scraping. Implements of this type belong to the early quaternary. The art is almost universally distributed. It is likely that wood in the form of sticks was also used, but wooden implements have not survived the ravages of time. The skill in handling brittle stone gradually increased and the forms became more elaborate and specialized. The shaping of tough stones by pecking, polishing and drilling occurs in Europe much later. Toward the end of the earlier palaeolithic period fire had been discovered and was presumably used for obtaining warmth and for preparing food. On account of the difficulty of obtaining fire it is carefully kept in rotten logs or other forms of slow-match. It is claimed that the Andaman Islanders do not know how to make fire, that they keep up their fires continually. Fire is most frequently produced by drilling, less frequently by a sawing or cutting motion. It seems likely, therefore, that the production of fire was learned from these processes, and at a time when drilling and cutting tools were made of wood. The use of fire for preparing food is difficult to understand. Without long experience scorched and burnt animals found after a fire of natural origin cannot have been attractive, on account of the strangeness of taste and smell; and it is difficult to see how it happened that the experience was presented with sufficient frequency to become attractive. It is still more

difficult to understand the discovery of boiling. Many modern tribes boil by throwing red hot stones into water contained in a box or basket. This is presumably the earliest method of bringing water to a boil. It would seem that the only experience that could lead to this result is presented in cases where a stream of lava runs into a pond, bringing the water to a boil and cooking the animals living in the water. To make use of this observation the invention of containers for water and the appreciation of boiled food were required. Experience with fire also led to its use in hardening, shaping and hollowing out wood.

An important step in the development of implements was made when two pieces were united together. The earliest stone implements were merely held in the hand. Later on the stone was attached to a handle and in the further development of tools the elaboration of the handle is almost more important than that of the working tool. The art of combining different parts into a unit is also the basis of sewing and weaving.

The invention of pottery was not made until after the end of the palaeolithic period. Even now pottery making is not universally distributed. The discovery may have been made when food was roasted or steamed in underground ovens made in clayey soil. People whose habits require a frequent change of dwelling place do not use pottery on account of its fragile character. It presupposes permanence of a dwelling that, however, may be occupied only seasonally. In many parts of the world pots are made of strips of clay that are built up spirally, in coils. This suggests a relation of the technique of pottery to that kind of basketry which is made by sewing together coils of fibrous material.

Wood, bark, bone and horn are shaped by cutting, shaving, drilling and polishing. They are bent by steaming. Pieces are joined together by tying, sewing and pegging; sometimes also by gluing.

The use of skins required methods of preservation to avoid rotting and stiffening of hides. Both mechanical and chemical means are applied to this end, such as scraping, application of various substances for curing, and smoking.

The invention of basketry may have antedated that of pottery. Weaving by intertwining coarse materials and coiling by sewing together spiral coils of fibres or twigs are the processes applied. Weaving of cloth developed through the substi-

tution of spun hair or plant fibre for stiff intertwined materials.

The most important step in industrial development was the discovery of the use of metals. Locally pure copper was used like stone. It was hammered into shape. In Babylonia and Egypt the reduction of copper ores was known in the fourth millennium B.C. About the middle of the third millennium bronze, an alloy of copper and tin, appeared in Egypt, first containing a small amount of tin which gradually increased to about ten percent. In America bronze was also invented and used in Peru and in parts of Central America. Iron appeared in Egypt in the twelfth century before our era. It has never been used in aboriginal America, except in a few cases in which pure meteoric iron was available.

The impetus to many inventions must have come in the work of procuring food and shelter. The gathering of roots led to the development of instruments for breaking the soil. The effective accumulation of seeds, berries and other vegetable food supplies was made possible by the construction of receptacles which also facilitated the preservation of supplies and their protection against the ravages of small animals. Bark, wood and basketry were used both for carrying and preservation.

The killing of animals brought about the development of means of overtaking and overcoming them. Weapons for throwing served to wound them; pits and traps were employed for holding and killing them. Masses of skeletons of the mammoth and of horses found as remains of periods in which hunting implements were still apparently ineffective suggest the use of pits and of the battue. The use of pits is also suggested by some palaeolithic rock paintings. At the end of the palaeolithic period bow and arrow, spears and throwing sticks were in use. Harpoons and fishing implements were also made in this period.

The various inventions were also utilized for the construction of dwellings. Simple mechanical devices for lifting heavy beams must have been developed in connection with the erection of habitations intended to shelter many individuals. Stone architecture was a late development. Stone enclosures or more complex structures were probably first used for graves, as evidenced by early stone circles, stone cysts and dolmens. Stone architecture developed in the eastern Mediterranean and in the plateaus of South and Central America.

The acquisition of tools, implements and

other property requires means of transportation in cases of removal from one place to another. In addition to the receptacles already mentioned which were carried by man, means for transporting heavier loads on sliding conveyances were required. Domesticated animals were used for carrying and hauling, and special means of locomotion on snow, like sledge and snowshoe, were invented. The wheel is a comparatively late acquisition confined to parts of the Old World. The use of regular routes of travel, such as are found also in animal life, created trails through the woods and brought about the discovery of fording places. Much later, trails were artificially developed and rivers or valleys crossed by primitive bridges. Navigation must have developed at an early time. Without it the peopling of islands would have been impossible. The simplest forms of transportation by water are rafts made of wood or bundles of floating plants, but we also find at an early time the dug-out. The canoe made of ribs covered with bark or hide and the plank boat are later inventions.

A number of inventions deserve special mention on account of their complexity and the proof they give of the ability to profit by the observation of complex phenomena. Bow and arrow belong to this group. In Europe the rock paintings of Spain give evidence of the inventions of these before the close of the glacial period. In all probability the experiences gained with spring-traps may have helped to develop the invention, but there could have been no immediate observation that would lead to it. The intricacies of the flight of the Australian boomerang were observed in the peculiarities of the flight of thrown sticks, but it required an incredible amount of experience and of acute observation to discover that the inclination of the planes of the two arms towards each other is the condition under which the observed and desired movement is obtained. Another unusually complex invention is that of sailing by the wind which the Micronesians use: the shifting of the mast; reversing of bow and stern in order to keep the outrigger on the lee side; but particularly the difference in curvature of the sides of the Marshall Islands canoe which serves to prevent the turning of the canoe in the direction of the outrigger. The Negroes of Africa reduce iron ores in furnaces in which the ore and charcoal is placed in alternating layers and in which increased heat is produced by a system of bellows that supply the furnace with a constant current of fresh air. This art is widely spread

over Africa and may be a discovery of the Negroes, although arguments may also be given for its invention in western Asia. The early cultivation of plants and domestication of animals disclose other practises that are difficult to understand as discoveries due to the observation of nature. The artificial pollination of the date palm and the gelding of animals may serve as examples. Many other similar inventions may be mentioned in which the opportunity for discovery by observation is exceedingly remote.

Economics. In primitive society men and women cooperate in gathering the necessary food supply. A fundamental difference due to physiological causes is found in their activities. Childbearing women during pregnancy, when nursing young children and when caring for a number of children, are less mobile than men. They are unable to move rapidly over great distances and hence their lives are spent in or near the camp. For this reason we find that among all hunters and fishermen the men occupy themselves with the chase and with fishing, while the women gather vegetable products and slow moving or stationary animals that are within reach of the camp, and perform all the work that pertains to the camp. Secondly it follows that the men prepare the utensils for the chase while the women work on the utensils and implements used in camp. Stone and wood are the principal materials used by the hunter. Hence the man performs work in stone and wood. He uses hammer, knife and drill. Normally the woman works on meat, skin and fibre; she cooks, preserves food, prepares skins, spins, sews and weaves baskets and cloth.

The woman's work is largely devoted to the gathering and handling of plants. In technically somewhat more advanced communities the whole agricultural work falls to her share while the men are unfamiliar with the raising of plants.

It is therefore probable that the art of agriculture was developed by woman. The men, on the other hand, are constantly occupied with the chase. In technically more advanced communities they take care of the domesticated animals. Accordingly it seems likely that domestication of animals was developed by the men. The theory that domestication developed from the habit of keeping pets, a practise common, for instance, in South America, is not tenable, because an essential trait of domestication is the free reproduction of the herd, a condition not found among pets, and also because pets are cared for by the women, who do not occupy themselves with domesticated animals.

In most cases the typical division of labor according to sex continues until some type of labor that in simple communities is performed by man is utilized for the further development of agriculture. This is the case when irrigation or building of terraces is required, or when the help of domesticated animals is introduced in agricultural work, as in ploughing.

Even in simple forms of society there is further division of labor according to individual preference. When hunting and fishing are practised, some men devote themselves by preference, or even exclusively, to the one or the other occupation. Among the Chukchee there is a differentiation between maritime dwellers who are sea hunters, and reindeer breeders. Members of the same family may belong partly to the coast people, partly to the inland reindeer breeders. Some individuals, skilled in particular industrial pursuits, devote themselves to these and furnish their tribe fellows with the products of their labor. The person who is endowed with the power of curing disease and of communicating with the supernatural world is a professional in the strict sense of the term.

In somewhat more complex societies, as among the Africans or Polynesians, there is a much more highly developed division of labor. No longer are all the industries carried on in each family group, but there are definite trades; in Africa, particularly, the blacksmiths, in Polynesia the carpenters and boat builders.

When the social structure is more complex, hereditary groups may take over definite functions. In North America some special division of the tribe may furnish the warriors; in the region of the Great Lakes of East Africa agriculture and herding are carried on by distinct hereditary divisions of the tribe. On Vancouver Island whaling was the privilege of a small group. In

the civilized states of America, as well as in Egypt, the division of trades was very elaborate.

The feeling for property rights is not confined to man. Both individual and social property rights are found in the animal world. The woodchuck owns its hole; the bird its nest, sometimes even its surroundings; the squirrel and mouse their stores of winter provisions. Animals defend their property against strange individuals or groups. Eagles drive away other birds of prey, monkeys and kangaroos have their own limited territories which they defend against invasions. In all groups of primitive man there is a feeling for property of the individual in objects made or constantly used by himself, and of groups in the territory they occupy. Food, while individual property, is generally shared with members of the group. The individual has absolute control over objects made or constantly used by him, as long as their destruction does not involve loss or danger to others. Human property differs from that of animals in being transferable in the form of presents or exchange. Property is not only individual or tribal; it may also belong to tribal divisions (see *infra*). The tribal territory may be so subdivided, and social groups may have common property interests in other valued objects. Many of the individual or group property rights might better be called social privileges. Individual property or an individual privilege in which a group has a claim of participation must pass from the holder in the case of death, or sometimes even during his life, to other members of the same group. These conditions are expressed principally in the customs regulating inheritance. The range of objects that may be considered as property is very wide. Not only material objects are property, but also songs, tales, position and other privileges.

Since even in the simplest forms of society a differentiation of occupation exists, at least in so far as the sexes contribute different parts of the sustenance and are engaged in different industrial occupations, and since furthermore a pronounced feeling for property rights exists, we find also customs regulating the exchange of produce. In the small family both parents generally contribute to the support without consideration of the value of the goods, but when the family breaks up, the man and the woman each claim as their property what they have collected or made, and in general in exchanging goods or making presents to outsiders their respective ownership manifests itself. These conditions are more complex whenever a more elaborate

division of labor exists, so that a family is no longer economically self-sufficient. In most forms of primitive society such exchange is made by barter or by rendering service. M. Mauss has pointed out that the fundamental principle of exchange is the obligation of accepting a present and the consequent obligation of the return of an equivalent. The Chukchee reindeer-breeder exchanges furs for seal-meat and thongs obtained from members of his own family or from others who dwell on the seacoast. The Indian of the western plateaus exchanges dressed deer-hides for dried salmon. Another form of payment occurs when valuable appliances are borrowed for purposes of productive work or when in a cooperative enterprise one individual furnishes the needed appliances, such as a canoe or nets. In these cases the participants share in the product of their work but yield to the owner of the appliance a specific privilege. A member of a family group is also considered as a valuable asset. This finds expression both when compensation is demanded for a death caused by an outsider and in the payments or service demanded in exchange for the privilege of marrying a girl and taking her away from the family unit. Although other attitudes play an important role in these cases, their economic import must not be neglected.

There are few tribes that are absolutely self-sustaining. Most of them obtain from neighbors some necessities, such as salt and iron in Africa, and shells and, in later times, horses in America. In extreme cases a tribe may take up a specialized occupation and rely for everything else upon its neighbors. An outstanding example are the Toda in India who have given up almost everything for a milk industry. Exchange with neighboring tribes is generally by barter, in cases of mutual fear by silent barter, the objects of exchange being deposited and left, either to be taken up and exchanged or refused by the second party. When barter is more regular, a standardization of values occurs. In Africa, on the islands of the Pacific Ocean, and in many parts of America values are measured by standards. Some of these may be used for practical purposes, while others, although useful, are handled only as representations of values, that is, as money. In Africa salt, iron in various standard forms, and cattle serve as standards of wealth. All of these may be used, while the usefulness of shell money which occurs, for instance, in Africa, Micronesia and America is restricted to the manufacture of

ornaments. On the north Pacific coast of North America blankets, canoes and copperplates representing certain values are in use as standards. In some parts of East Africa wealth is measured solely by cattle, not by any other kind of possession.

Wherever a highly developed system of exchange exists, we find also systems of credit. The amount given is repaid by exchange or in money value at a later time, either without or with interest. When it cannot be repaid in substance it may have to be repaid in service. An extreme form of this institution is found in the bonding of members of a family in debt, which prevails in many parts of Africa.

War, notwithstanding its numerous other affiliations, must be considered as a form of economic activity, for most wars or raids among primitive people are waged for the acquisition or retaliatory destruction of property, including the values inherent in human life. The horse stealing raids of American Indians, the cattle and slave raids of Africans, and the plunder of villages in Melanesia are examples. In arid countries the possession of water, among herders the need of pastures, have led to armed conflicts between those who try to acquire them.

Consult: Cunow, H., *Allgemeine Wirtschaftsgeschichte*, vol. i- (Berlin 1926-); Schmidt, M., *Grundriss der ethnologischen Volkswirtschaftslehre*, 2 vols. (Stuttgart 1920-21); Koppers, W., "Die ethnologische Wirtschaftsforschung" in *Anthropos*, vols. x-xi (1915-16) 611-51, 971-1079, a general historical review.

Social Organization. Man everywhere lives gregariously, and a local group varying in size forms a unit firmly coherent in its relation to outsiders. In the same way that many gregarious animals form closed societies which do not admit strangers of the same species, so in primitive society every local unit forms a closed society hostile to all outsiders. This is clearly expressed by the frequent custom among primitive tribes of designating themselves as "human beings," all outside groups by specific terms. There are probably no tribal units in existence now that have exclusively hostile relations to their neighbors, but suspicion and avoidance are very common. The feeling of community of interest of the members of a closed group is characteristic of even advanced types of human society.

Free sexual relations and marriage must be clearly distinguished. Free relations are the result of sexual passion, marriage involves property relations. Although in many cases free

premarital sexual intercourse is forbidden and, if discovered, punished, there are numerous cases in which it is permitted or is even required, except among individuals who belong to an incest group (see *infra*). Marriage is often easily terminated, until in old age a more permanent relation between husband and wife develops. Personal attachment between two young individuals is often passionate and accompanied by jealousy, but temporary. Abnormal sexual habits, such as homosexuality, have been observed among many primitive tribes. They may be explained as an effect of domestication common to man and highly domesticated animals.

The position of the individual in the social group is determined by age, sex and membership in a fixed subdivision usually consisting of descendants of a common ancestor, immediate or remote, known or assumed.

Infants and young children are dependent upon adults and therefore occupy a special position in the social unit. As they acquire greater independence they may continue to be grouped by age classes or they may merge in the general population. The old-age group which loses its economic independence is also often set off from the active population. The period of adolescence and complete maturity also brings about the formation of separate groups. Individuals passing through these stages at approximately the same time may continue throughout life as a group that retains its individuality, as in East Africa, or they may be advanced through a number of groups differing in functions and characteristics. Generally the more detailed age groupings are more pronounced in the male sex than among females.

A fundamental difference prevails in the social position of the sexes. It is due to the difference of their biological functions and the resulting difference in economic position, men being hunters, women food-gatherers; men herders, women agriculturists, at least in most of the simpler forms of human societies (see p. 82).

Since on hunting expeditions and in war men work in groups which need a leader, social recognition of leadership belongs almost always to the man. Woman's work is more commonly individual or at least does not require leadership.

In the daily life of primitive man the family group is the most important unit. It consists normally of parents and children. The family forms the economic unit in the life of hunters who live in infertile areas, for each group needs

a large area for its sustenance. The mother cannot procure sufficient food for herself and her children, and a male is needed to maintain the family. The human family unit is analogous to the family unit of animals.

The relations to one another of individuals constituting this group depend upon the relation of the family to the larger social group of which they form a part. In almost all forms of human society the family consisting of parents and children forms an incest group, sexual intercourse between parents and children and between brothers and sisters being forbidden. The mature children must seek mates in other family groups. If the original family does not separate completely after the establishment of new families by the children, relations are established that give rise to a great variety of forms. These complications are bound to arise where families do not live in temporary isolation, but occupy jointly a village or a limited territory in which communication is frequent.

Three fundamental forms controlling the interrelation of families are possible and do occur. First, the family may be a firm unit and the relations of the children to father and mother may be the same. This is called a family with bilateral descent. Second, the man who marries a daughter of a family may come in as a stranger and may remain more or less an outsider, while the daughter's children may be considered as born to the family and members of the family. In this case there is a close relation between mother and children, a loose relation between children, relations-in-law and father. Third, the son may take a wife from another family into his own family, so that his children will be members of his own family while his wife remains an outsider. In this case a close relation exists between father and children, a loose relation between mother and children. The second and third are families with more or less clearly recognized unilateral descent, the second matrilineal, the third patrilineal.

Social status is largely a reflection of such relationships. In a small community in which bilateral descent prevails, the concept of the family as an incest group cannot be extended over the later generations. If it were, the whole tribe would become a single family and marriages in the group—endogamic marriages in the tribe—would become impossible. All marriages would have to be with foreign tribes, and tribal exogamy is the concomitant of this condition.

In both cases of unilateral descent consciousness of family relationship in later generations may be preserved and leads to large exogamic groupings in the tribe. This is possible only in two cases: when the terms of relationship are not individual, but extend over classes of individuals so that a whole group may be recognized as members of an incest group or as outsiders; or when a certain symbol holds together the whole large family group, such as a name, a particular kind of dress, or practises others do not share.

When a common term is used for the mother and all her sisters, when the children of this group of sisters call one another brothers and sisters and when this designation is carried through the generations, combined with the conceptualization of brothers and sisters as an incest group, the tribal unit will be divided into a number of exogamic units. If the tribe is small and no accessions to these groups occur and if, for some reason, they do not split up, this will ultimately lead to a dual division, owing to the unavoidable extinction of most of such lines of descent. The same result is obtained when the unity of the later generations is preserved by a common name or by some other symbol. Conditions of this kind are generally designated as totemism. The totemites share a name, a symbol, beliefs or rites.

The principles according to which relationship may be conceptualized vary considerably. The most frequent principles are sex of person spoken of; generation; collateral or direct line of descent; relative age; sex of an intermediate relative, as in terms of maternal or paternal descent or in terms of affinity through wife or husband, sister or brother; sex of speaker; death of an intermediate relative, as, for instance, death of mother in the term used for a maternal uncle; social rank. The combination of these principles of classification vary considerably, and many of them may be omitted. When the principle of generation is omitted, all the males of the mother's line (in the case of matrilineal descent) may be designated by the same term. When sex of the intermediate relative is considered, there may be four terms for cousins, as father's brother's child, father's sister's child, mother's brother's child, mother's sister's child. In the same way as in our term "brother" relative age is disregarded and the term is reciprocally applicable, generation may be disregarded, so that one term may designate the reciprocal relations between uncle and nephew or between grandfather and grandson.

The incest groups vary in character. When the fraternal and paternal nomenclature is extended, as described before, and exogamy is adhered to, the whole group so designated forms an exogamic unit and there is a sharp distinction between parallel cousins (that is, the children of two brothers or of two sisters—in matrilineal society the children of sisters, in patrilineal society the children of brothers) and cross cousins (that is, children so related that the father of one group of brothers and sisters is the brother of the mother of the other one). The former, as brothers and sisters, belong to the incest group; the latter belong to different families and may, or even must, intermarry.

Endogamy is found in local units. Marriages outside of the tribe or village may be forbidden. In India the basis of endogamy is caste, based largely on occupation. In Australia its basis is generation. Individuals of even generations may not marry members of odd generations. Both in India and Australia endogamy is combined with exogamy. In India the caste is subdivided in exogamic family lines. In Australia the whole tribe is divided into generations and into exogamic moieties. There may even be a double system of these, giving rise to a most complex system of marriage regulations.

In most cases the regulations preventing sexual relations in the incest groups are felt as absolutely binding. There are, however, cases in which sexual relations in the incest groups are considered as condonable.

Exogamy and endogamy are extreme expressions of a differentiation of behavior in the group of relatives both by consanguinity and affinity. Some relatives may be exceedingly free in their social intercourse. They stand in the positions of "joking" relationship. Others have to be treated with extreme respect, which sometimes takes the form of absolute avoidance. This occurs particularly between mother-in-law and son-in-law. It is generally felt as an expression of respect. Avoidance and familiarity are related to actual or potential sexual relations between the sexes, or to community of sexual interests.

From the interrelation between social position and sex, social leadership generally belonging to the men, a peculiar contradiction results in all cases of matrilineal descents. When social position belongs to a family line it cannot be transmitted from father to son, but must be inherited from a male of the mother's family, that is, from the maternal uncle. This is frequently the source of the avunculate, although

prominent position of a woman's brother in the family unit may bring about similar conditions without matrilineal descent. Since often the mother's brother does not belong to the same economic unit as that to which his sister belongs, a certain weakness is inherent in the avunculate and it is liable to give way to systems in which inheritance and descent are combined in the same sex.

The constitution of the family is dependent upon the numerical relation of mates. There are four possibilities: several men may be mated with several women; one man with several women; one woman with several men; or one man with one woman. All these forms do occur, most frequently the union of one man with several women (polygyny), or of one man with one woman (monogamy). The two other forms, polyandry and group marriage, are rare.

If polygyny is combined with permanent matrilocal residence, the wives must necessarily be sisters; if combined with patrilocal residence, they do not need to be related. In Africa polygynous households consist of a number of separate houses, each being presided over by one woman. Since marriage is always accompanied by a transfer of property rights, often by exchanges between the two families, or presents or payments made by the groom's family to the wife's family, the relationship between husband and wife is involved in these transactions. In case of payments made by the groom's family, the deceased wife's sister may be claimed as a substitute; or after the death of the husband his brother or son from another unrelated wife may claim the widow. In other cases the deceased husband's brother may be claimed as a substitute by the widow's family. Both these forms, sororate and levirate, are expressions of the property relations between families. In some cases they lead to apparent group marriages between brothers and sisters. In exceptional cases women of different generations, such as mother and daughter, may be involved in these relations.

There is no evidence that any one of the four forms of marriage was the original form. It seems rather probable that according to economic and other conditions of life one or another form developed.

Groupings consisting of relatives by consanguinity and affinity occur everywhere. In many primitive societies, particularly in those in which the local unit embraces larger numbers of individuals, other types of social groupings oc-

cur, some very firmly knit, others rather loose. These groups are held together by their social functions: occupational, political or religious. In many cases we find clubs embracing age classes of one sex, particularly young men. In others military societies occur which have definite duties or privileges in military undertakings. In extreme cases, as in some parts of Africa, they form regular regiments in an army. In still others they perform police functions. There are also societies that are pitched against one another in games and those charged with religious activities, like the shamanistic societies of the Pueblo Indians or those of Melanesia.

In some cases these societies are identical with the groups based on actual or supposed consanguinity, or they must be recruited from their membership. For example, one of the divisions of the Omaha tribe which is viewed as consanguineous is charged with the defense of the camp circle, another one functions as keeper of the sacred objects of the tribe. The societies are likely to surround themselves by secrecy, their activities, teachings and functions being known only to members. Often all the adult males form a group from which women and children are rigidly excluded. Intrusion is punishable by death or other heavy penalties. Meetings of the society are held in secrecy and guarded by the use of musical instruments, such as the bull-roarer or whistle, that keep outsiders away. Hereditary rights to membership in a society imply either that the society is identical with one of the family groups or sibs, or that its members are selected exclusively from one family or sib.

As the family groups may have associated to themselves a name, symbol, privilege or rite, so the societies are apt to assume the same characteristics. Probably all societies have names. Many are characterized by their dress or, like the African military groups, by the decoration of their paraphernalia. The societies of British Columbia differ in rank and possess privileges. Whenever a religious element is involved in these organizations, they have rites of their own and supernatural protectors appear in the same way as in family groups. The forms of these phenomena are analogous to those of totemism, but attach to a society instead of to a group considered as consanguineous.

On account of the secrecy involved in the organization of these associations new members must undergo a course of instruction. Its character differs according to the character of

the society and to the manner of acquisition. When membership is attained by purchase of a seat in the society and when the prerogatives of the society are purely formal, no elaborate instruction may be necessary because the society has no esoteric teachings. In other cases the novice may be compelled by the older members, or by the prevailing custom, to join and there may be an elaborate course of instruction, often connected with complex rites of initiation. In this case the entrance into the society is often coincident with adolescence and is of a religious character (see p. 102).

The size of the social group varies. In extreme cases all the males may form one association. The other extreme is reached when a social group consists of a single individual only. Between these extremes all possible sizes of groups are found.

The existence of any type of grouping is accompanied by stratification of society. Single individuals, as well as social groups that claim any kind of social distinction, are segregated from the general mass of the population. The segregation does not need to be based on the forms of society referred to before, but may be due to individual prominence in some capacity: experience and skill as hunter, fisherman, herder, agriculturist or warrior and consequent wealth; skill in arts; in helping the sick; in real or supposed possession of unusual qualities. All these may insure to the individual unusual prominence in his community. A different kind of stratification results from the privileges or powers of a closed society, in which all the members on account of their membership form a privileged class. When membership is determined by consanguinity we have a hereditary nobility. In other cases a hereditary priesthood or other similar forms result. The unity of the tribe depends largely upon the functions and mutual relations of these associations. When their activities are correlated, or when they form an integrated series in which leading individuals or associations control the others, the tribe will form a well organized unit. The control may be based on friendly relation or may be forced, as in cases of subjection of one class by another, or of a conquered unit by its victors. When they are uncoordinated the tribal unit will be loose.

In the limits of the group, no matter whether it is held together by consanguinity or by functioning, the members are subject to the rules of the group, which are supreme. Breach of these rules is resented or even punished. In this sense

the group is analogous to the state, from which it differs because it does not unite all the members of the community in one whole, subject to common rules of behavior. The more complete the coordination or subordination of these groups, the more will the political organization approach our concept of a state. Since cohesion of the groups implies constant contact, possibility of communication and local contiguity are necessary elements in the formation of well integrated groups. Examples of uncoordinated groups are family groups or sibs that require mutual aid among the members and joint responsibility against outsiders, as in blood feuds, religious societies, like those of the Dakotas, which are held together by similar revelations, and many of the military societies of the Plains Indians. Coordination and subordination are characteristic of many of the politico-religious societies of Africa and of political organizations such as the League of the Iroquois. In some cases the separate, uncoordinated groups may form temporarily coordinated associations, as in the case of the Plains Indians during the buffalo hunt, when they are subject to a particular society that performs, temporarily, police functions, or the sibs of the Kwakiutl, which, whenever a village has dealings with another village as a whole, become a unit.

A., *The History of Human Marriage*, 3 vols. (5th ed. London 1921); Frazer, J. G., *Totemism and Exogamy*, 4 vols. (London 1910).

Law. Ordinarily the individual is not restrained in his actions so long as their effects concern only himself. As soon as his actions have a bearing upon the well being of his fellows a customary behavior is demanded which may be designated as customary law. Its domain is intimately associated with the general social and religious concepts of the community. Property rights are guarded. When a forbidden marriage is planned and it is believed that it entails dangers to others, it will be prevented. When the breach of a tabu is considered as

dangerous for the community, observance will be enforced. Interference with the individual who plans an action detrimental to himself may emanate from his family or his friends. He may also be shunned, because his action is condemned, or because intercourse or contact with him may be dangerous. Behavior in these cases is not regulated or enforced.

In many cases, particularly in America, customary law is obeyed merely in deference to public opinion. There are no restrictions that serve the enforcement of the law, excepting police organizations that control communal undertakings such as the gathering of fruits, the hunt or war. These are charged not with judicial function but merely with executive control. In Africa, on the other hand, a most elaborate system of judicial procedure is found almost everywhere. It uses the taking of evidence, the oath and the ordeal, and is strictly comparable to European and Asiatic forms of procedure.

Where public opinion controls, the individual crimes that affect the community may result in the killing or driving out of the criminal, or ways may exist by means of which the effects of the crime may be warded off—by purification or other religious means. There is no set punishment or compensation. When the evil results can be warded off there is no punishment. On the other hand, infractions that affect the interests of individuals or of groups of individuals are settled by revenge taken on the perpetrator or on a member of his group, according to the principle of retaliation. The damage inflicted in revenge must not exceed the original one. In other cases compensation may take the place of retaliation. A life may be redeemed by payments adjusted to socially established valuations. Wherever strong solidarity of a group occurs, responsibility is not individual but rests with the group. Actual law giving machinery and imposition of arbitrary fines are common in Africa but are rare or absent in other areas.

Customary law is binding only in the social group. The relations to outsiders are commonly unsettled, although in many cases customary law regulates intertribal commercial intercourse, and forms exist that provide for the avoidance or termination of hostilities.

Leisure. When the necessity of procuring food and shelter does not fill all the time of waking life, either because the food supply is plentiful and easily obtained or because the ample supply of one season is laid up and man lives in the intervening season on accumulated stores, the leisure time is spent in a variety of occupations. The total amount of tangible property that constitutes the possessions of a household depends largely on leisure time, on the permanence of abode and, in migratory tribes, upon facilities of transportation. The variety of household goods increases with the amount of leisure time. Besides this, time becomes available for activities that do not serve the immediate needs of life, and complications of technique, social gatherings and religious rites of various kinds have opportunity to develop.

In early childhood no contributions to the maintenance of the tribe are demanded and hence young children pass their time playing. Much of their playing is imitation of the occupations of their elders and a differentiation according to sex may be generally observed, the boys imitating man's, the girls woman's, work. Besides this, amusements in great variety occur: ball games, spinning of tops and plays based on personal dexterity or strength. Parents play with their young children, often accompanying the game by the singing of ditties. Adults also have games of individual dexterity, such as the making of string figures or contests in wrestling or running. Formal ball plays and racing according to set rules are common. Games in which the whole village may be divided into two units are often accompanied by betting. Games of chance, of the most varied character and played according to intricate rules, are found almost everywhere and lead often to a high pitch of excitement.

Consult: Culin, Stewart, "Games of the North American Indians" in *United States Bureau of American Ethnology, 24th Annual Report, 1902-03* (Washington 1907) 1-846; Groos, Karl, *The Play of Man*, tr. by E. L. Baldwin (New York 1901).

Art. The influence of leisure upon technique is most important. It is characteristic of almost all untouched primitive culture that the technical skill exhibited in all kinds of manufacture is very great. Slovenly work has no place in primitive culture. Even when the members of the family have to provide all their weapons, implements and utensils, these are made with skill. This is still more the case when the technique used in various kinds of manufacture is

the same for most of the needs of the people, as among the Californian Indians, who use basketry for all their household utensils. As more time is devoted to a particular industry, skill becomes greater, and when sufficient leisure is available, joy in the skill acquired leads to a play with the technique that is one of the sources of artistic form.

The mastery of technique results in regularity of outline and of surface in the manufactured object, and there is evidence of the satisfaction felt in their achievement. In some cases the virtuosity displayed in the manufacture is not visible in the resulting form. The satisfaction can therefore lie mainly in the pleasure given by the control of the difficult technique, only secondarily in the regularity of form. Pleasure in virtuosity is the stimulus that leads to the development of complex forms.

The fundamental lines found in all manufactured work are the results of technical processes. The straight line is rare in nature, but is produced whenever a fibre or string is drawn tight or when the same process is carried along by a sure hand. Regularity of curves and circular forms result in basketry and pottery; spirals, in the coiling of thongs, ropes and wire.

Rhythmic repetition is also a necessary result of technical skill, for the regularity of movement involved in skill leads to the regular repetition of the same forms. The more complex the group of technical movements that produce a form unit, the more complex is also the rhythm. Less intimately related to the technical processes is symmetry, which although not universal is of frequent occurrence. Symmetrical forms result in basketry and pottery, but they are not so definitely the results of technical processes as the straight line, the regular curve and rhythmic repetition.

Every technique, as locally developed, produces fixed forms because the same technical processes are employed by all. These forms constitute the basis of the local art style. Without fixity of form art is impossible. The increasing complexity of technique, due to the development of virtuosity, often directly produces surface patterns. This is particularly noticeable in basketry but occurs also in stone chipping, adzing of wood and hammering of metal, whenever the work is done in complex rhythmic regularity. It is necessary to assume that these forms were felt as attractive, for the further development of the surface by decoration does not follow directly from technical needs. It may

be observed that borders are emphasized, that prominent points are elaborated and that entirely adventitious forms are produced which have no relation to technical processes. These also follow fixed rules of arrangement. The mental effect of all these products is based entirely on the pleasure given by virtuosity and by a feeling for form.

Representative art has an entirely different source and appeal. It springs from the desire to represent some interesting object and its appeal is based on the contents and forms of the representation. So far as it is merely representation without skill, it has only the slightest relation to art. When executed with technical skill it has the double appeal of content and form. Representation can be made skilfully only in a technique in which virtuosity has been attained. The technique must therefore exert an influence over the form of the representation. The technical style will influence the style of representation. This may be particularly observed in weaving. The arts which allow the most naturalistic representations, on account of the flexibility of their materials, are pottery and carving. The most realistic representations are in the pottery of Peru or the Sudan and in the carvings of the Eskimo. In many other cases the rigidity of the art style will not admit realistic representation even in these materials. In representations of three-dimensional objects on a plane two methods are used, a symbolic one in which all those parts of the object are shown that appear to the maker as essential, without regard to their position; and a perspective one in which a view from a single viewpoint at a single moment is given. The former method is most rigidly developed in the art of the Indians of the north Pacific coast, the latter is characteristic of our classical art. Combinations between the two are frequent, as, for instance, in ancient Egyptian art in which the whole representation consists of a composition of a number of forms in perspective each seen from a different viewpoint.

Among many primitive tribes the association between technical form and representation has come to be so intimate that all forms are expected to be representative, so that apparently geometrical forms are given a symbolic meaning. In some cases this meaning is fixed for the whole community. In others there are great individual variations of the concepts suggested by forms. The symbolic meaning may be of intense emotional significance or it may be merely a name assigned to a form. In some cases

it can be shown that the meaning is read into a design which may be further elaborated according to the idea once suggested, or it may be an old representation which has become conventionalized by use or by the compelling force of an inadequate technical style or by the compulsion of stylistic requirements of space.

Art style is one of the "patterns" that characterize the thoughts and activities of every social unit. It is closely connected with motor habits, but no less with habits of formal arrangements. Every representation is subject to the molding influence of style. Its form is a result of the application of the style, and the style cannot be explained as a result of conventionalization of patterns. There may also be more than one style when different types of technique develop in a tribe, owing to a differentiation of occupations. More frequently one of the types of technique most productive of decorative forms imposes its style upon all the others.

On account of the close interrelation between technical skill and decorative art those parts of the population are the most productive and inventive that do most of the technical work. On the north Pacific coast the bulk of the industrial work consists in wood carving and is done by the men. In California the principal industrial occupation is basketry, which is done by the women. Hence the men are the creative artists in the north, the women in California.

Most primitive art is decorative. It consists of designs applied to useful objects. Works of fine art, made for the sake of art alone, are rare. Small representative carvings of the Eskimo and rock paintings and carvings of the Bushmen belong to this class. The paintings of glacial man also belong primarily to this class.

In some cases representations have a value only on account of the idea they express. This happens sometimes when objects are made for ritualistic purposes, to be discarded after the performance of the rite; or when the representations or symbols serve exclusively the purpose of communication. The symbolic devices used for the conveyance of messages, such as cowrie strings of varied forms in Africa, the signs set up along trails for the information of travelers, or the message sticks of Australia, are primarily means of communication or mnemonic devices. Sometimes they may have at the same time a decorative function, like the feathers of the Dakota Indians which, by the way they are cut and painted, express warlike exploits. The re-

cording of information by means of pictures has also no artistic aim and is in character generally quite independent of the art style developed in those types of technique in which virtuosity has been attained. Picture writing or its further development into ideographic or hieroglyphic writing assumes artistic forms only when transferred to other artistic industries, as in Central American architecture and painting, or where it is given permanent form in codices.

The conditions for the development of music and literature are different from those for the graphic and plastic arts, because they require a different kind of leisure. While hunting and food gathering, man cannot work with his hands. The time for technical occupation is when he is at rest. On the other hand, the imagination from which spring music and poetry is at work at all times when attention is not concentrated on a particular object. For this reason even those tribes that are poor in industrial and art products, like the Bushmen, have a large body of music, poetry and prose tradition.

In primitive culture poetry is inseparable from music, and the dance is generally accompanied by music and poetry. Poetry and the dance are dependent upon musical form. There are simple forms of song in which the musical notes are sung on meaningless syllables. In others a single word or a name may be interjected between the meaningless syllables. In still others the words are distorted so as to become adjusted to the musical phrasing. Only when the words express consecutive thought may the tune be adjusted to the words, by addition or omission of short musical phrases.

Rhythmic repetition, parallelism of structure, and emphasis are the forces with which primitive music and song operate. The rhythm of primitive music is often very complex. Music uses also sequences of pitch. In some regions the whole range of pitch is very narrow, not more than three tones; in others it is wide. Discontinuous intervals are used everywhere; continuous raising or lowering of pitch occurs as a mannerism of singing. The system of intervals is fixed, although not easily defined on account of the inaccuracies of singing. Almost all primitive singing is in unison. When men and women sing together it is in parallel octaves. Singing in parallel fifths or fourths is rare. On the Admiralty Islands singing in parallel seconds occurs. The intervals are not based on harmony and differ from the scales of the music to which we are accustomed. The accompaniment of song by

rhythmic noises—handclapping, beating of boards, drums or rattles—is universal, and rhythm is sometimes carried along by beating alone. The coordination of rhythms of singing, instruments and dancing is often intricate. A complication arises when the instrument that is struck gives several distinct tones, like the drums of ancient Mexico. A further development of percussion instruments is the xylophone. This and similar instruments occur commonly in Africa. Pipes occur in the form of Pandean pipes, as in Melanesia and South America, and as flutes of several tones. Although reed pipes are used as calls and whistles, their use as musical instruments seems to have been confined to the Far East and to Europe. String instruments occur only in the Old World. The use of instruments must have contributed to the development of harmony, to the fixing of intervals and to polyphonus music.

On account of the interrelation between body movement and articulation—a special form of body movement—it seems likely that rhythmic body movements release rhythmic articulations, that is, song. In this sense songs that consist of meaningless syllables may have their origin in rhythmic movement. On the other hand, the excitement engendered by song leads to movements that are related to the rhythm of song, so that in this sense the dance is conditioned by song. All formally regulated body movements must be classed as dance. The dance accompanying states of great excitement, while adhering to the general local dance pattern, loses in fixity of form; the more formal the dance, the more rigid its adherence to artistic pattern. We find among primitive tribes solo dancing, as in the Arctic tribes among whom dancer, drummer and singer are often the same person, or solo dancing accompanied by a chorus. The most frequent form is the dancing of groups of men or of women placed in definite order and all performing the same motions. When these motions are imitative, the dance approaches a dramatic performance. In some cases the dance movements are accompanied by significant gestures or consist of gestures expressive of the words of the accompanying song. We find even more fully developed pantomimic representations.

In more highly developed song the words give a connected meaning. Many of the trifling songs that have been recorded fail to give an adequate impression of primitive poetry because the visitor hears first of all what corresponds to the

street songs of our times. The subject matter of song is as varied as our own, although in the precarious life of primitive tribes the emotional connotation of the satisfaction of daily needs is infinitely greater than among ourselves. Hence the numerous songs describing in detail the emotional effect of the movements of animal and hunter or of the occupations of the food gatherer. The patterns of interest are very varied. Among the Eskimo we find songs describing the beauties of nature, a variety of songs relating to hunting, domestic affairs, quarrels, songs of religious import, and others expressing love for children, but hardly any love songs. Among some other tribes love songs are found. The language of religious songs or of other songs of serious import is sometimes archaic, or devices are used that make words appear different from the forms of ordinary usage. Metaphoric expressions, cumulative synonyms, parallelism of form, are used as artistic devices. Rhyme and assonance are rare except when they appear on account of repetition of words.

While most of the poetic forms are lyric, prose is either narrative or oratory adapted to public occasions. It is, however, not rare that oratory, as in the case of the laudatory oratory of Polynesia, takes poetic form. Impressive narrative may also assume a semi-poetic form by the regular repetition of meaningless syllables or by taking the form of a rhythmically organized recitative.

Narrative includes tales dealing with events in human society, animal tales, myths and the like. The forms vary according to local style and occasion. While human tales may be told in free form, the impressiveness of sacred myths may be increased by intimating rather than telling their contents. The form varies also according to the purpose of the narrative. Many Negro tribes like to associate their tales with a moral, as in our moralizing fable. In other cases the point of the tale may be etiological.

There has been much speculation regarding the origin of tales. It has been claimed that mythological tales are an immediate reflex of the anthropomorphic consideration of nature and that many apparently non-mythological tales are derived from myths. This theory is contradicted by the varied interpretation given to tales with mythological significance by various tribes, according to their particular mythological interests. Thus the mythological value appears as attached to the preexisting tale. While mythological concepts result from the anthro-

pomorphic interpretation of nature, plots of mythological tales seem to be transferred from the human sphere to mythology. According to this view folk tales and myths must be considered primarily as products of the art of narrative. Their religious significance is a secondary development. Since the tale is an artistic unfolding of the happenings in human society, it must reflect the habits and conflicts of life of the society in which the narrator lives. Themes like the conflict between father-in-law and son-in-law, or between stepmother and stepchild, must be considered from this angle. It is but natural that the tales reflect intimately the cultural life of the people, although in some cases, as in Europe, it may be the cultural life of a passing or past period. At the same time their character depends upon the play of imagination with the conditions of everyday life. Exaggerations of strength, size, abilities; fulfilment of wishes; conditions the opposite of what we are accustomed to, are features of imaginative narrative the world over.

There are fundamental differences in the forms of tales. Among most primitive tribes the single tales are rather short. Often they are connected by being concentrated around a single character, like the transformer tales of many tribes, the tales of Reynard the Fox, or the raven tales of eastern Siberia. A sequence may be established by letting the hero travel through a certain district. Only in rare instances are tales united by an inner bond, like some of the origin tales of Polynesia. Still more rarely are they cast in poetic form and united into epics, like those of ancient Greece and of the Orient.

Mention should be made of two minor literary forms: the proverb and the riddle. These are highly developed in some parts of the world, as in Africa, almost absent in others, as in America.

Knowledge. A curious contrast is presented

between the actual control of nature based on precise knowledge and the manifold beliefs and practises of primitive man. The inventions previously described are all the result of acute observation and of practical experience. The knowledge of primitive man extends over the whole field of his experience. He is familiar with the habits of animals and with the life of plants, so far as his practical experience brings him into contact with them. The regular movements of sun and moon are known and lead to calendar systems based on the celestial phenomena, but closely related to seasonal occupations. Measures of space and time are the more elaborate, the more extensive their use in technical occupations and in the regulation of daily occupations. Counting is the more elaborate, the more important the number of equal objects in everyday life. The north Californians have standard measures marked on their hands to determine the value of chains of shells; the tribes of British Columbia count their standard values by tens of thousands; the ritualistic calendar of the Pueblos determines with a fair degree of accuracy the time for the performance of the religious acts that occur during a series of years. Principles of geometry are empirically known and applied in the squaring of boxes by giving the diagonals equal length or by making a right angle by equally dividing the base of an isosceles triangle and connecting the center of the base with the apex. Geographical knowledge is embodied in the sailing charts of the Marshall Islanders, which mark the locations of islands, directions of the swell and of currents and cross seas, and in the charts of the Eskimo. All these illustrate the ability to learn from the observation of complex phenomena. The measuring of time and space and the art of counting indicate the beginnings of a systematization of knowledge which, however, has not led to a systematic observation of the regular connections between objective phenomena and the recognition that the objective world cannot be controlled by thoughts or acts that enable us to influence our fellow men.

Religion. As we distinguish objects by size as large or small, by formal expression as beautiful or ugly, by ethical value as good or bad, without being able to draw a sharp line between the concepts of these opposites, so we distinguish between degrees of power over the outer world or of the power of the outer world over us. Ordinary ways of applying power are a matter of everyday experience. Extraordinary ways of applying power are wonderful. The emotion aroused by the latter is one of the chief elements of religious feeling. The line between the ordinary and extraordinary is indistinct. What is ordinary to one person or to one cultural group is extraordinary to another. Thus it is difficult to circumscribe the field of religion in a satisfactory way, because the same ethnic phenomena may have a religious connotation or may lack it entirely. The cure of a patient by extracting from his body the supposed cause of disease, like a piece of bone, may be a purely practical act. It may also be associated with strong emotional feelings related to an unusual heightening of the everyday powers of the practitioner. In the former case it has no religious connotation, in the latter it has. It is necessary to consider in the study of religion all activities and thoughts that are sometimes associated with the feeling of unusual power—either one's own or one that confronts one's self—even if in other cases they lack this connotation entirely. For this reason treatises on religious belief do and must include descriptions and discussions of the greatest variety of customs based on the assumption of relations which we do not recognize as founded on physical cause and effect, or on those in which physical cause and effect arouse a strong emotional attitude associated with the feeling for the existence of heightened powers. The specific character of this emotion is expressed by the attitude of man to those things which he considers sacred, as opposed to the ordinary secular life. From this point of view the religious side of ethical and aesthetic emotion will also find its proper place.

It is convenient to consider religious phenomena from two angles, as thought and action. The former gives us the general view of nature, which in a sense we might call the dogma; the latter, actions related to the dogma or those releasing religious emotion.

There are two widely distributed concepts of

power, the one anthropomorphic and clearly conceptualized, the other vague and defined with difficulty. Languages like the American Algonquin, which classify the objective world in what is human-like (i.e. animate) and what is not human-like (i.e. inanimate), give the clearest evidence of the importance of the anthropomorphic viewpoint. It may be that some of those which, like the Eskimo, do not know of any differentiation, recognize human qualities in the whole world. The interpretation of events according to subjective experience is, however, general. As we are only too apt to explain the motivation of action in our fellow men in accordance with our own mode of thinking and feeling, so primitive man, with his lack of controlled experience, explains the events of the outer world as voluntary actions which, if helpful to him, are friendly, if impeding his plans, hostile. This is not to be conceived as a rationalization but as an automatic reaction, like the unrepressed action of a person in our civilization, child or adult, who vents his spleen on an inanimate object that has been the cause of some accident. The dogmatized development of this attitude may lead to the belief that the whole world is animate, or to the belief that human-like beings inhabit all objects and that the objects obey the orders of these beings rather than that the objects themselves act. This is in part the Eskimo conception of the inanimate world. Animals, on account of the many qualities of behavior that they share with man, are most commonly considered as strictly analogous to powerful human beings.

The anthropomorphic viewpoint is conversely applied in the conceptualization of inner experiences and of the phenomena accompanying death. In some languages qualities or even habitual actions are conceptualized as objects so that they appear as nouns. It is not by any means necessary that the occurrence of such concepts should lead to an imaginative process by means of which they are given concrete form and anthropomorphic character, but it affords ready opportunity for such development. We still feel the force in the use of metaphors based on a concrete form given to a state or attribute. Hunger, courage, love, sin, consciousness, death, are, owing either to traditional usage or to poetic imagination, endowed with qualities, particularly anthropomorphic qualities, and with concrete form. Sickness is often conceived as a concrete object or a living being that enters a body and may be removed again, or as an enemy

who attacks the body and against whom man may be defended. Sins or transgressions are commonly considered as impurities that may be removed by mechanical means. The skill of a hunter may be objectivated and exist as an object or as an anthropomorphic being leading an existence independent of the hunter himself. Other qualities, particularly life, power of action, personality, are indissolubly connected with the living individual. Their conceptualization, particularly their anthropomorphic conceptualization, leads to the varying concepts of the soul. It is not rare that several of these occur at the same time, so that we have an apparent multiplicity of souls, in reality a multiplicity of different anthropomorphic aspects of life.

Since those qualities, conditions and functions which we construe under the term "soul" are conceived as substances, body and soul have separate existence and their lives are not encompassed in the same period of time. This seems to be the essence of the belief in immortality. The soul may exist before birth and continues to exist after death, for the memory of the substantiated qualities of a person does not end with his death. The intangible memory-image of the deceased arises suddenly, and vanishes again when the calls of everyday life repress imaginative thought and day dreams. It partakes of all the features of the departed and he appears in his daily garb and in his daily occupations, all of which have, therefore, continued existence. The conflicts between everyday experience and the continued existence of these images lead also to the concept of the remote country of the dead. The detailed development of all these concepts into individual systems of mythology depends largely upon specific ideas developing in a tribal unit or introduced through intertribal relations. Anthropomorphism is the expression of a lack of differentiation between the self and its sense experience.

Fundamentally distinct from anthropomorphization is the conceptualization of power as an attribute of objects. The concept is necessarily vaguer than the concrete anthropomorphization. A stone, a piece of wood or a tree is conceived as having the quality of bringing good luck or misfortune; a particular place or a particular time is endowed with "sacred" qualities; a word or a symbolic action may have the quality of power; or finally all nature may have the quality of exerting power. The awe inspired by any of these phenomena is a response to their immanent power that may have a depressing or an inspiring effect.

Such powers may also be discovered in man. The seer who discovers the future, the twin children who control the weather, the warrior who has slain an enemy, the woman during menstruation or after child birth, and the dead are endowed with powers, helpful or dangerous. Those who have helpful powers perform religious functions in the community and are intermediaries between those without powers and the anthropomorphic beings or the vague powers whom they are able to control.

Both types of reaction to the outer world occur continually side by side and independently. They flow together in so far as the quality of power is ascribed to the anthropomorphized concepts.

Only the anthropomorphic aspect of the world lends itself to the development of mythological concepts, for the human forms participate in human activities. The animals speak and act like men, the wind travels through the world, the sun is dressed in shining garments, the soul leaves the body. For this reason mythological concepts reflect necessarily the pattern of tribal life. At the same time they are transfigured by imagination, human conditions being exaggerated or a contrast being created to the conditions existing in the known world.

Many mythological concepts that are found distributed widely all over the world may be the immediate outflow of the anthropomorphic viewpoint. This seems particularly true in connection with the conceptualization of the soul, of animals as human beings, perhaps also in the readiness with which active natural forces, like sun, wind and thunderstorms, or everchanging natural forms, like the moon, are given human forms; but mythological concepts are so varied and they are so readily influenced by imaginative suggestion that their actual development in each locality can be understood only by an analysis of their complex growth, due in part to the ever changing formulations given by imaginative minds in the course of generations, and in part to suggestions that come from the outside through cultural contact.

The mythological tales attached to the anthropomorphic characters are even more involved in their origins. All these tales, when stripped of their mythological trappings, are clearly human, novelistic tales. It is often assumed that these tales are an expression of the naive contemplation of natural phenomena. Their distribution and the variety of mythological purposes served by the same tale suggest that ordinarily the

reverse process has occurred. The anthropomorphic characters seem to have fitted a pre-existing tale or to have suited peculiar human situations that are often the topic of conversation. These were transferred to the mythologic characters. There is ample evidence of the wide diffusion of tales and of the variety of their mythological applications.

Most mythologies attempt to account for the beginnings of things, for the origin of human inventions and for the regulations controlling life. The mythological imagination relating to origins is always satisfied with the existence of things as they are now in another concrete or conceptual world, from which they are brought into the world of man piecemeal or altogether; from a concrete world by heroic or crafty visitors, from a conceptual world through projection into objective existence by a creative will power, as in Semitic mythology; or by actual manufacture according to the preexisting idea. In some cases the beginnings of our era are marked not only by the beginnings of those conditions that make life possible but also by the introduction of the difficulties that beset human life, while the previous period did not know hunger, sickness and death. The correlated idea of an end of our period with recurrence of desired conditions is not so frequent.

While the vague concept of power as an attribute has not the necessary definiteness to lead to the formation of myths, it occurs constantly as an important element of mythical tales, just as it appears in human life: the mysterious qualities of space, exemplified by the contrast between inland and sea, mountains and plains, or between the cardinal points; of time as shown by the power or sacredness of certain hours or days, of the solstices, midnight or new moon; of numbers, as in the formal number of repetitions of an action, of the success of the third brother, of the fifth son or of the fourth attempt to reach a goal. In many of these cases the purely aesthetic pleasure in repetition may be felt as no less important than the mystic relations of space, time and number.

The forms of religious activities and those of religious concepts are interrelated. An extended group of religious activities serves the purpose of obtaining success in undertakings; in other words, they are designed to obtain the fulfillment of wishes. Magical acts are performed to control immanent powers of objects or of mythical beings. In the performance of a process resides the power to have the same process re-

peated in another desired place or on another object. This is magic by analogy. To dissolve the clay figure of an enemy in running water causes the enemy to waste away. The symbolic act by means of which an end is to be attained varies in character among different tribes and according to the ends to be attained. Fertility of plants or animals is promoted by sexual symbolism, rain and wind by symbolic, imitative actions. An object and all its parts are felt to be so intimately related that an action affecting the part will affect the whole. Particularly the human body is so keenly felt to be one with the hair, nails and excretions, with objects that have absorbed some of the exhalation or perspiration, that their maltreatment will immediately affect the body itself. Whatever is done to the part affects the whole. A spell can coerce anthropomorphic beings on account of its inherent power. The action of amulets is based on their qualities that exert a control over other qualities or anthropomorphic beings. An amulet makes it permissible to visit uncanny places and protects against the attack of spirits. On the other hand unlucky objects may thwart favorable influences.

Generally all kinds of power, conceived as qualities or in anthropomorphic form, are unable to overcome the defiling influences of the unclean, particularly of mourners and menstruating women, sometimes also of a murderer or of a warrior who has killed an enemy. Hostile powers may be overcome by magical acts.

It depends entirely upon the attitude of the performer of a magical act or of the wearer of an amulet whether his behavior is individually of a religious character or whether he looks upon it unemotionally purely as a relation of cause and effect, from his point of view as a practical or scientific process. When accompanied by the emotional state induced by the awe, respect, or feeling of sacredness of the qualities utilized, it is religious.

The devices used for influencing anthropomorphic beings are naturally parallel to behavior by which human beings are influenced: to entreaty, presents or compulsion. These devices applied to anthropomorphic beings are prayer, sacrifice and compelling spell. Formality of prayer and sacrifice are often necessary because their power is believed to be immanent not in the act as such but in its form. The stronger this concept, the more rigidly controlled is ritualistic behavior. Ritualistic accuracy of behavior is sometimes insisted on because of the inherent power of the precise

action; at other times it is interpreted as a requirement imposed by anthropomorphic powers. Simple forms of ritual are merely an expression of custom, like tabus or forms adhered to in gatherings. In most of these the religious explanation is due to rationalization of a prevailing custom, although the rationalization may produce new parallel customs. Examples of such rationalized customs are the food tabus. Some South African tribes observe food tabus, because the eating of the forbidden fruit would cause the teeth to drop out prematurely. There is no reference to a supernatural being. The Eskimos must observe their tabus because the concretely conceived transgression fastens itself to the hair of the anthropomorphic giver of food animals, annoys her and causes her to withhold the food supply.

Many ritualistic acts designed to increase the power of the performer require a heightened emotional state. When power is to be obtained from anthropomorphic beings, their grace is secured by rigorous purification, fasting, dancing and, in some cases, by self-torture. These may lead to a trance in which the desired power-bestowing vision is secured. The person who seeks a vision and the practising shaman work themselves up into a state of high excitement. Other ritualistic acts are perfunctory and lack the emotional connotation. Of this character are most of the tabus and proscriptions which are automatically repeated day by day: small, regular sacrifices and prayers and the like. The greater the formalism, the less the accompanying religious excitement.

Rituals are apt to increase in complexity, the larger the number of participants and the stronger their differentiation in regard to specific powers. Their specific forms depend not so much on religious concepts as on their relation to social forms and aesthetic impulses.

The terms animism, mana and other related ones have been avoided here, because their present use seems to obscure the essential point, the difference between the approach to the "supernatural" from the viewpoints of power conceived as anthropomorphic and of power conceived as an inherent quality of objects.

glaubens (Leipsic 1916); Hauer, J. W., *Die Religionen*, vol. i- (Stuttgart 1923-); Marett, R. R., *The Threshold of Religion* (2nd ed. London 1914); Durkheim, E., *Les formes élémentaires de la vie religieuse* (Paris 1912), tr. by J. W. Swain (London 1915).

Ethics. The impression given by the moral behavior of man in different cultures is that of a great variety of standards. The slight valuation of human life, anthropophagy, slavery, torture of captives, suicide, looseness of sexual relations, represent attitudes that seem fundamentally different from our own standards. Notwithstanding these differences in behavior the ethical motivation does not show analogous differences. A sharp distinction is always drawn between the members of the social group and outsiders. The standard of ethical behavior toward members of one's own group is regulated by subordination of the individual to group interests and by recognition of the rights of other members of the group. Mutual helpfulness in the group is demanded; inordinate egotism that overrides the interests of fellow members is resented. The Eskimo shares his game with unsuccessful hunters, the clan of Alaska Indians supports one of its members in his undertakings by gifts or loans of valuables. Property rights in the community are respected. General subordination under the rules which keep the society going is expected. These rules are not binding outside of the closed social unit. Behavior toward the alien depends upon the form of this concept. In most primitive societies the very fact that only members of one's own group are designated as human beings indicates that, at one time at least, a specific difference was felt to exist between them and aliens. With increasing recognition of the similarity of interests between aliens and group-fellows, the utter disregard of the interests of the former has been weakened, although the feeling of difference is an active force even up to the present time.

The social obligations that develop in intimate family life, particularly the instinctive relations between mothers and helpless children, not always only their own, may be observed everywhere. When the social customs interfere with them, as occurs in numerous cases, ethical conflicts arise.

In primitive society the standard of behavior is fixed by a common culture. As in the Homeric *epos* the relations of man and the gods were recognized beyond the possibility of a doubt and the ethics of behavior were regulated according

to a well integrated culture, so it is in primitive society, which does not favor individual freedom of thought. The individual does not seek an ideal, it is given to him. Pressure in regard to conformity in belief is very rare, but individual actions contrary to custom are so often conceived as detrimental to the common weal that they are resented and suppressed.

The most serious offenses within the social group are murder and bodily harm; infraction of property rights, including adultery; witchcraft and transgression of tabus or other regulations that concern the whole community. In cases of individual or group conflict retaliation is felt as an ethical duty. In some cases the feeling of respect for the rights of fellow members turns into jealous envy of every person who is in any way prominent, by wealth, wisdom or skill. This is a characteristic feature, for instance, of African society.

Consult: Westernmark, E. A., *The Origin and Development of the Moral Ideas*, 2 vols. (2nd ed. London 1912-17; Sutherland, A., *The Origin and Growth of the Moral Instinct*, 2 vols. (London 1898); Hobhouse, L. T., *Morals in Evolution* (3rd ed. London 1915).

THE INTEGRATION OF CULTURE. All the various aspects of human life: bodily form, language, culture, as well as the environment in which man is placed, are interrelated, and the form of culture is a result of this integration. In many aspects of culture the mutual influences are strong, in others weak.

Race and culture. No adequate proof has ever been given showing that the different behavior of racial groups is organically determined. The wide range of differences between individuals and family lines constituting a local race, and the occurrence of identical types in related races, have been pointed out before (p. 75). It has also been stated that this overlapping of forms is much more far reaching in physiological and mental functioning than in anatomical form. The apparent differences in mental reaction of races obtained by students of experimental psychology may be ascribed as well to differences in upbringing and in cultural experience as to differences in anatomical structure. The differences in results of tests taken on people of the same descent, but living in different environment, seem to prove the importance of environmental as against organic determination. In groups as much alike as the various types of Europe no anatomical difference can be found that would explain the varying behavior of

different social or local groups. The achievements of different races have been adduced as proof of organic differences. The primitive culture of the Australians, contrasted with the high civilization of Europe, is taken as proof of the lower mental status of the Australian. While it is not possible to disprove the argument in this case, it is certainly not applicable in a comparison of north Europeans, central Europeans, south Europeans, Mongols and Malays. In these cases the historic conditions are so different, the organic basis of mental life so similar, that it seems arbitrary to explain differences as due to biological factors. It is possible that the frequency of creative genius may not be the same in all races and that slight differences in the distribution of various forms of functioning occur, but it cannot be shown that any of the existing races is, on account of its hereditary character, unable to participate in any one of the existing civilizations.

Consult: Gobineau, Arthur de, *Essai sur l'inégalité des races humaines*, 2 vols. (2nd ed. Paris 1884), bk. i tr. by Adrian Collins (London 1915). A general survey of the literature relating to mental differences of races has been given by Theophile Simar, *Étude critique sur la formation de la doctrine des races au XVIII^e siècle et son expansion au XIX^e siècle* (Brussels 1922). Unfortunately the author does not discriminate clearly between the theory of racial and cultural characteristics, so that many of his statements are misleading. Among representatives of the theory of lack of correlation between racial descent and cultural life may be mentioned Hertz, Friedrich, *Rasse und Kultur* (3rd ed. Leipsic 1925), tr. by A. S. Levetus and W. Entz (London 1928); Zoltschan, I., *Das Rassenproblem* (3rd ed. Vienna 1912); Boas, F., *The Mind of Primitive Man* (New York 1911), and *Anthropology and Modern Life* (New York 1928); Lowie, R. H., *Culture and Ethnology* (New York 1917). A medial position is taken by Hankins, Frank H., *The Racial Basis of Civilization* (New York 1926).

Environment and Culture. Attempts have been made to explain the whole cultural complex as due to environmental influences. This is not possible. In every society the elements that influence the actual course of cultural change are many and varied. We may expect to find an influence of environment upon culture, but the fact that a variety of cultural forms occurs at various periods in the same environment is sufficient indication that the environment alone does not determine specific cultural forms. The American Indian who did not know the use of iron and coal was influenced by his environment differently from his European successor. Increased knowledge changes the relation of man

to his environment. Before horses were introduced, the western prairies played one part in the life of the Indian. After the introduction of horses they played another part, and after the disappearance of the buffalo and the introduction of cattle, still another. Their introduction was determined by historical happenings that had no relation to the environment, but that changed the environment itself. Environment modifies culture, and culture modifies certain aspects of the environment. The limiting effects of environment are clear. The absence of vegetable products limits the culture of the Eskimo, the absence of snow that of the inhabitants of Central Africa. Absence of wood on the steppes, of stone on atoll islands, of fish in the desert are all limiting factors. On the other hand geographical conditions are a creative factor to a very slight degree only. Fertility of the soil does not produce agriculture. It helps in the development of agriculture where the art is known. The presence of large herds of reindeer has not created domestication in America, although Siberian tribes living in an analogous environment have domesticated the reindeer. The presence of iron ores in America has not developed American metallurgy, although in Africa the ores are utilized. The influence of environment is confined to modifications brought about in pre-existing cultural forms. The direction which the stimulus takes depends upon cultural factors. The hard snow of the Arctic enabled the Eskimo, but not other Arctic tribes, to invent the vaulted snow hut. The occurrence of clay does not everywhere lead to the development of pottery. When it does occur, the excellence of the technique is not dependent upon the abundance and quality of material but upon the general economic demands and the technical and artistic activities of the people. Given a certain type of culture, the effects of environment may be traced in many important aspects of life, but only in this sense can environment be considered as a determinant. The periodicity of the seasons, the habits of animals, the general configuration of the country all exert their influences. Periods of activity and of leisure, the location of villages, movements of the tribe from one locality to another, the forms of means of transportation and the limits of political units are so affected. Thus the seasonal ripening of fruits followed by periods in which vegetable food supply is not available and the annual movements of spawning fish followed by periods in which the supply of fish is inadequate determine the habits of

people dependent upon fruits and fish. The position of villages near streams that abound in fish or on the seacoast; the periodic migrations of tribes that hunt migratory game; the use of the sledge and snowshoe in snow covered countries; the political isolation of communities in secluded valleys, are determined or at least favored by local conditions. The food supply also controls the size of communities that do not import food products and thus exerts an indirect influence over social and political organization. The experiences with which the imagination of the people occupies itself are furnished by the environment in which they live. Hence their traditional tales, their metaphorical expressions and even their religious beliefs require, for a full understanding, a knowledge of the influence of environment upon a preexisting culture and of its importance as furnishing much of the available sense experience.

No less effective is the geographical position of a people that makes possible or hinders cultural contact and the dissemination of ideas and inventions. Attention has also been directed to the stimulating or enervating effect of climate upon the individual, but no direct relation between these conditions and the development of early culture has been proved to exist. Analogous cultural forms exist or existed in tropical Africa and in temperate North America, and advanced cultures flourished in India and in Europe.

Consult: Ratzel, F., *Anthropogeographie*, 2 vols. (2nd ed. Stuttgart 1899-1912); Semple, E. C., *Influences of Geographic Environment* (New York 1911); Vidal de la Blache, P. M. J., *Principes de géographie humaine* (Paris 1922), tr. by M. T. Bingham (New York 1926); Huntington, Ellsworth, *Civilization and Climate* (3rd ed. New York 1924).

Population. The density of population is determined both by cultural achievements and by environment. A population that is entirely self-sustaining, that does not receive food supplies from the outside, is limited by the food supply that can be secured from its habitat. An Eskimo tribe that relies upon sea hunting, or a Californian tribe that lives on acorns, cannot increase permanently beyond the limit that can be sustained in the most unfavorable years. These limits are higher where agriculture or herding occur. When the food supply is ample, the density of a population may increase, provided there are no other checks, like war, infanticide or disease. If at the same time the food supply is seasonal or so easily secured that time for

leisure remains, the total number of individuals who can devote their time to occupations other than the mere obtaining of food and shelter increases, and opportunities for the development of new cultural achievements are given. In general a correlation between density of population and diversity of cultural traits may be observed. Political organization depends upon the size of social units and upon the density of population.

It is possible that the natural limitations of population may have contributed to devices for an artificial retardation of the natural increase, by infanticide, abortion and restrictions of sexual intercourse, although it does not seem likely that these are primary causes.

Consult: Ratzel, F., *Anthropogeographie*, 2 vols. (2nd ed. Stuttgart 1899-1912) vol. ii, p. 95-256; Carr-Saunders, A. M., *The Population Problem* (Oxford 1922).

Language and Culture. The interrelations between language and culture have been touched upon before (p. 78). So far as inventions, institutions, art and religion go, they are not far reaching. Their importance lies in the influence of language upon speculative thought, upon directions followed in attempts to give explanations for customs; still more in the emotional value of words that serve as symbols, like those for supernatural power or sacred objects and acts. This, however, is not a specific characteristic of language. It is common to all symbols.

Interrelations between Other Cultural Phenomena. The relations between geographical environment and fundamental economic conditions are close, and in most cases the environment acts through the intermediary of economic conditions. These, being a part of culture, are much more closely related to other manifestations of cultural life than environment. The occupations by means of which man obtains food and shelter determine the directions in which his discoveries and inventions develop. The sea-hunting Eskimo has developed his boats and weapons because his whole life is based on the procuring of sea mammals for food and for heat; not that the specific forms are determined by the economic occupation, but the concentration of attention upon this occupation gives the opportunity for new achievements. The cattle breeder and agriculturists acquire their experiences and make their technical inventions in those domains of human activity upon which their attention is concentrated.

The amount of leisure depends upon economic conditions. The more easily food and shelter are secured, the more ready is man to devote his time to play with hands, tools and mind. The complexity of cultural activities increases, therefore, with favorable economic conditions.

While it cannot be maintained that social forms are determined by economic conditions, the two aspects of cultural life are indissolubly related. In a region of ample food supply in which the maintenance of life depends solely upon physical skill and in which a sparse population allows everyone to find a productive hunting ground, a differentiation according to rank or wealth is not likely to occur, except in so far as orphans, widows and old people may be thrown upon the mercy of their friends and relatives. When the produce of the country does not allow all to share equally, when specially favored spots are claimed as property, the equality is disturbed and economic and social differentiations are found. Thus the development of property concepts, the organization of the family and of occupations, the occurrence of societies with social or religious functions, are all intimately related to economic conditions. The forms of organization cannot be explained as due to economic necessity, but their development may be favored or hindered by economic needs, while they themselves always influence economic life. Thus property in land may be vested in the whole community. Among hunters and food gatherers all may have equal rights; or the labor bestowed upon a particular locality—like the building of traps, burning over of ground or tilling the soil—may give to an individual or to a group a temporary or permanent right to the use of a particular piece of land. The property rights in these cases depend upon the constitution of the cooperative unit, whether a single person, a family, a sib or a society. In extreme cases, as in some African tribes, all property in land may be vested in a single ruler.

Whenever the transfer of property involves future obligations on the part of the recipient, the transaction is public and gives opportunity to the development of ritualistic behavior. African marriages, the potlatch of northwest America and the elaborate Kula Ring of the Trobriands are examples.

Intertribal relations are strongly influenced by economic considerations. It has been pointed out that war is often a means to the acquisition of necessary or desired property. Peaceful contact

is commonly based on mutual economic interest, on the regulated exchange of produce which may lead to the establishment of regular markets, as in Africa or on the islands in Bering Strait where Asiatic and American tribes meet for barter.

The assumption made by Lewis Morgan and his followers of a close correlation between forms of family organization and other cultural traits is not borne out by the fuller data that are now available. We find the small bilateral family among the Eskimos, unusual complexity of the tribal organization among the Australians. In North America the division of the tribe in a few exogamic sibs is rather characteristic of the agricultural tribes, bilateral families are characteristic of many hunting and fishing tribes.

The terminology of blood relationship and of affinity is only to a small extent an expression of biological relations. It is primarily an expression of social relations. Assuming exogamy as an exceedingly ancient institution, as indicated by its universality, the extension of terms of the incest group beyond the small family will exert an influence over the development of sibs, as indicated before (p. 86). The mutual influence between the early terms of relationship and their application to wider circles may have established larger exogamic groupings and these in turn may have stabilized the linguistic categories.

A close connection may be traced between organization on occupational and political lines and technical progress. The greater the variety of technical processes and the more complex the technique, the more developed is social specialization, as among the Africans where the trade of the blacksmith is often carried on by a separate social class; or in Samoa, where the carpenters are a group by themselves. Specialization in technical pursuits of the two sexes or of individuals of special skill is universal. In the latter group those who are believed to be possessed of supernatural powers form a distinct class. Political organization depends in part upon the type of activity of the tribe, in part upon the size of the population. Recognized leaders who wield authority are found wherever communal undertakings occur that demand leadership for their success. The closer the contact between individuals and families whose interests are liable to come into conflict, the more frequently do we find more elaborate political organization. Its form is not determined by these conditions but by historical relations or other particular conditions.

Religious beliefs pervade the whole domain of cultural life, for technical, economic, legal, social and artistic manifestations are filled with beliefs and actions that have a religious background. Since the success of every action depends upon skill, upon the power of adequate performance, it may be thwarted by hostile or helped by friendly powers. The relation of man to the supernatural pervades, therefore, his whole life. Technical and economic activities are often accompanied by prayers and tabus; and everything pertaining to social organization is sanctified. Customary law is largely occupied with the observances of religious proscriptions.

More essential than these interrelations between various aspects of culture is the unification of culture according to definite patterns. In a number of primitive cultures occur fundamental attitudes that dominate the thoughts and behavior of the society. Thus the Indians of the northwest coast of America are entirely dominated by the desire for rank and social prestige to be attained by lavish distribution of wealth. All the actions of men and women, from childhood on, are dominated by this thought. The methods of social preferment are fixed and may be observed in the procedures connected with social gatherings, shamanism, ceremonies and war. Many Melanesians seem to be under the sway of a similar pattern, in which, however, display of property is more important than distribution. The Indians of the plains are dominated by the idea of advancement of social standing by means of warlike exploits and military glory of a set type, with emphasis upon personal bravery. Their feeling for military prowess as a dominant characteristic of their lives is entirely distinct from that of the headhunting Dyak. In contradistinction to these types of culture that stress social standing, Dr. Bunzel describes the life of the Zuni, Dr. Mead that of the Samoan, who strive to merge individuality in the mass. Dr. Benedict has described in a most instructive manner the distinction between the "Dionysian" orgiastic pattern of the lives of most Indians and the "Apollonian" formal pattern of the Pueblos. In many cases the general cultural pattern is weak and the culture seems to us thin. Nevertheless the strong influence of patterns of thought or behavior may be felt, even in these cases, in more limited aspects of culture. An example is the art style to which every newly invented pattern conforms. The pronounced styles of New Zealand, those of the tribes of the Amazon region, of the basketry of the Indians of

various parts of California or the local character of mythology and folklore are of this kind. The strong influence of the pattern appears also in social organization and religious ritual. When one section of a tribe is designated by a name, all have names; when one believes in a totemic ancestor or protector, all have this belief; if tabus are proscribed for sibs, they are likely to be proscribed for other types of social groupings.

The integration of culture here discussed is not identical with the correlations established by early investigators, like Lewis H. Morgan. It is also distinct from those correlations between language, economic life, social organization and religion which W. Schmidt and W. Koppers derive from a comparative study of cultures. Notwithstanding their attempt to reach historical results by an analysis of cultures based on the occurrences of numerous analogous phenomena, they end with an evolutionary series in which many aspects of culture appear firmly associated on each developmental stage.

(Berlin 1912-24) vol. iii, pt. i; Schmidt, W., "Die Genitivstellung in den nord- und mittel-amerikanischen Sprachen" in International Congress of Americanists, 21st congress, *Proceedings*, pt. i (The Hague 1924) p. 287-304, and "Zur Genitivstellung als Ausdruck der geistigen Einstellung" in Anthropologische Gesellschaft in Wien, *Mitteilungen*, vol. lviii (1928) 234-36.

Education. Children grow into the integrated culture largely by imitation. Their play is based on imitation of the activities of their elders and they participate at an early age, at least partially, in many of the industrial and social activities of the community. Formal education does not occupy much time, but it is not lacking. Behavior according to tribal standards is rigorously exacted and breaches are not passed over lightly. The breach of an important tabu, like intrusion into a secret religious society, may even be punished by death, however innocently committed. All this does not make the development of unruly gangs impossible. They may even be encouraged as a means of developing a domineering and warlike spirit. As soon as children are capable of taking part in the industrial activities of the tribe, they are expected to do so. Girls take charge of their younger brothers and sisters, assist in household duties, and learn the industries carried on by women. Boys participate in the work of the men. At the

same time moral instruction is given directly, by explaining those types of behavior that are considered right, respectful behavior before elders and supernatural beings, or arrogance toward inferior classes; the proprieties of behavior in everyday life; liberality or parsimony; craftiness or truthfulness. Often the moral teaching is attached to an entertaining tale which may be pointed toward a moral, or may be merely illustrative. An important part of the education of the young is connected with ceremonies of initiation, for in many cases the secret beliefs and rites are divulged to them at this time. The rites also impose severe hardships upon the young. They develop and test their endurance. The function of most of these rites is to make the young full participants in tribal life. The corresponding ceremonies through which the girl has to pass are generally less educative, but hinge upon the magic power of the first menstruation. Still the educative features are not absent. A special feature of the adolescent rites of boys and girls is the preparation for special activities. A boy may strive for means that make him a successful gambler, shaman or warrior; a girl for skill in an industry or in her home work. Sometimes skill in special activities is secured in childhood. The Eskimo shaman may impart power to a child by holding it in his lap. In New Caledonia the navel string cut on a hard stone makes the child hard like a stone in battle; in Vancouver Island, when fastened to the baton of a good singer, it makes the child a good singer.

THE STUDY OF CULTURES.—*Evolution and Progress.* The early anthropologists, like Spencer, Tylor, Morgan and Lubbock, who developed their theories under the stimulus of Darwinian evolution, observed correctly the increasing complexity of cultural forms, the progress of knowledge and the elimination of antiquated forms. On this basis the theory of the evolution of culture appeared to them as a continuous process. They erred in assuming a single unilinear evolution which may be discovered by means of the study of examples collected at random from all parts of the world. To give one instance, both Tylor and Spencer, each from a single fundamental idea, tried to develop the whole religious structure, although Tylor at least recognized diversification in later development. It is the picture of biological

development in which diverse life forms spring from the same source. Extreme evolutionists even assumed a unilinear development according to which every existing primitive and advanced culture may be given its proper place in a single ascending line. At present we recognize that cultural phenomena rarely have a single source. Economic life has two fundamentally distinct sources in the occupations of man and woman, from the combination of which agriculture, with the help of domesticated animals, later develops; the graphic and plastic arts develop from virtuosity in technique and from attempted representations which flow together and determine the later course of art; in religion are found the two fundamental ideas of power as an attribute of objects and as one of anthropomorphic beings. Besides this, in the further course of historic development, contact with foreign tribes plays an important part, so that the general picture is one of culture arising from multiple sources that unite, branch out and flow together among themselves and with remote lines.

While the general evolutionary scheme is no longer tenable, the problem of progress remains. Observation proves that the inventions and knowledge of man have extended with ever increasing rapidity, and it is possible to speak of progress in technique, in successful exploitation of natural resources and in knowledge, for every step taken is an addition to previous knowledge. Cases of loss of previous knowledge are comparatively rare and, for mankind as a whole, temporary. It is much more difficult to speak of progress in any other cultural activity, except in so far as those aspects of cultural life that contradict the advances of knowledge gradually disappear. The lack of change in fundamental ethical attitudes has been mentioned (p. 97). Progress in social organization refers generally to a better adaptation to economic conditions and ethical requirements as understood according to the general state of knowledge.

Diffusion and Independent Origin. Discussion of the problem of independent origin or diffusion of cultural traits has played an important part in the history of anthropology. The significance of diffusion is now generally recognized, abundant proof being available through the evidence of prehistoric archaeology, of early history and of the distribution of cultural phenomena. The gradual spread of bronze and iron in Europe, the evidence of mutual in-

fluences between Europe, Central Asia and the Far East, the distribution of inventions relating to navigation among the tribes of the Indian and Pacific Oceans, the distribution of Indian corn and its cultivation in the two Americas, are cases in point. There is, however, still much uncertainty in regard to the degree of similarity that constitutes proof of historical identity, and also in regard to the interpretations of locally isolated phenomena for which no historical contact seems likely. Some investigators claim for these independent origin, others historic connection. In many cases conclusive proof seems impossible. A detailed study of continuous distributions gives fairly certain results in regard to late contacts, while in many cases the direction of diffusion is determined with difficulty. Thus the interpretation of the history of the megalithic structures of western Europe depends upon an answer to the question whether they are imperfect forms suggested by a knowledge of Aegean structures or whether the latter are an elaboration of the cruder forms. In a case of this kind prehistoric archaeology may give an ultimate answer, while in the distribution of an art, custom or belief that extends fairly evenly over a wide area, but in varying perfection, a categorical answer based on distribution alone cannot be given. Neither is it possible to claim that the region of the fullest development of a cultural form must be its original home. As animal forms have become extinct in a district where they first appeared and flourish now in other continents, so cultural forms may originate in one area, become extinct and live in a remote district. Only in cases of the occurrence of easily recognized fragments of a cultural trait in discontinuous spots adjoining an area of its continuous distribution may we conclude with some certainty that it is recently introduced. A chronology based on distribution alone will always be full of uncertainties.

Inferences regarding early diffusion must be based on our experience in regard to stability of customs. The assumption of stability extending over exceedingly long periods is the fundamental basis of the *Kulturkreise* constructed by Frobenius, Graebner and Pater Schmidt. The basis of their argument is that wherever a sufficient number of independent analogous forms are found in remote areas, these are definite proof of an early historic connection. When in this manner the disconnected, surviving traits of one of the original culture forms have been isolated, the inference is drawn that all mixed

forms are more recent. The original forms are furthermore assumed to be those that are farthest removed from the original home of man—in South Africa, Australia and South America—and on this basis a time sequence is determined. While we must accept the methodological viewpoint, namely that wherever a sufficient number (quantity) of entirely independent elements of identical form occur, these are likely to be of common historical origin, nevertheless the proof of the permanence of the features compared has not been given. Observations on modern primitive cultures show that cultural traits which according to this theory are assumed to have remained stable since earliest times are undergoing constant changes. Neither inventions nor practises nor ideas remain stable under changing environmental or historical conditions. The theory would have to be substantiated by proof showing that those features for which great antiquity is claimed remain stable under varying conditions and over long periods. Stress is laid, for instance, on the square or round forms of houses. The American Athapascans have not retained their house forms, but these vary from square wooden structures to conical tents. In Polynesia, notwithstanding analogy in structure, the Samoans have round or elliptical houses, while house types of most of the other island groups are square. The social organization of tribes is not stable, but undergoes changes—often rapid changes. This is proved by the diversity of systems of relationship in closely related tribes and by such changes as are evidenced by the present status of the Bella Coola and Kwakiutl of the north Pacific coast of America, or by the contrast between the cattle breeding Bantu of east Africa and those of west Africa who lack cattle.

The theory minimizes the possibility of the independent origin of similar ideas. Graebner, with whose name the theory is particularly associated, denies its existence. A few entirely isolated occurrences seem convincing: the looking glass of obsidian of the Romans and of British Columbia and Mexico; the paddle with swallow-tail point on the coast of Oregon and on the lakes of Mecklenburg in Germany; the *enema*, by means of a tube with mouth piece, of the Bella Coola and of modern times; the scales of ancient Peru and of the Old World; sun dried bricks in the Orient and in America; the writing of numbers, by giving values to each unit according to its position, in Yucatan and in our method of writing; the small arrows used for

bleeding in Africa and in Asia. It is difficult to give historically valid examples of the independent development of inventions, because our civilization has been for a long time richer than that of primitive people and because the popular knowledge of elements on which new inventions are based is not well known. Thus the safety pin seems to have been reinvented after it had been in general use during the bronze period. Still it is mentioned in Germany by Hans Sachs in 1568. The jew's harp was recorded as a new invention in 1673, although there is evidence that it was known in 1535. The winding of twine in Polynesian fashion was reinvented in New York, but a patent was denied on account of the use of the method by the Polynesians. The history of invention and discoveries proves that in a given stage of culture analogous discoveries are bound to occur. This should apply also to primitive people who live under similar conditions and who are confronted by similar problems.

There is also lacking a clear definition of identity. A careful analytical study would justify the rejection of many assumed identities. The development of square and round houses does not need to have followed the same course everywhere. The invention of boards and their use for house building necessitates angular structures. The use of two parallel inclined wind sheds also leads to the construction of angular houses. Totemism is not by any means the same everywhere, either in character or in origin. Australian and American totemism are analogous neither in form nor in concept. In small tribes two class systems may develop through a reduction of multiple divisions. Others are based on the dual organization required in games in which the whole tribe participates and which may have entered deeply into the social structure, or upon the contrast between peace and war functions, between the sacred and the secular. These forms vary so much that comparability must be proved in every case. Shamanism is a generalized term which includes many different concepts of the relation between the shaman and the supernatural world.

Cultural activities in adjoining territories are often similar in form, but differ in their significance. In North America the uniformity of the art of the prairie tribes and its individuality when compared with the art of other districts prove a common historic origin. Nevertheless the types of symbolic meaning given to the same forms are strongly differentiated. The ritual of

the sun dance is essentially the same, but not its meaning. In the explanatory or ritualistic use of the same mythological notion each tribe shows its individuality. Similar observations have been made in regard to the culture of Polynesia, where similar objective features have been retained in distant islands, although their social connotation is not the same. This is true, for instance, in all that pertains to canoe building. It may be inferred from these and other similar observations that, on the one hand, actions are more stable than their significance; on the other hand, that it is easier to adopt a new mode of action than a new system of thought. As among ourselves, a certain institution or other form of behavior may continue for a long time while with changing culture its meaning changes; on the other hand, foreign forms may be copied but filled with a meaning that conforms to the mental habits of the society that adopts it. The explanation of a custom given by a people at any given time must always be considered primarily a psychological one. It is very rare that the psychological explanation actually coincides with the historical development of the custom. All these considerations stand in the way of the acceptance of the *Kulturkreis* theory, which is based on the assumption of the permanence of correlations of supposedly identical cultural traits, the identity of which has not been safely established and which in modern primitive cultures prove to be unstable.

Consult: Ankermann, B., "Kulturkreise und Kulturschichten in Afrika" in *Zeitschrift für Ethnologie*, vol. xxxvii (1905) 54-90; Frobenius, Leo, *Ursprung der Kultur* (Berlin 1898); Graebner, F., *Methode der Ethnologie* (Heidelberg 1911), and "Die melanesische Bogenkultur und ihre Verwandten" in *Anthropos*, vol. iv (1909) 726-80, 998-1032, and "Kulturkreise und Kulturschichten in Ozeanica" in *Zeitschrift für Ethnologie*, vol. xxxvii (1905) 28-53; Schmidt, W., "Kulturkreise und Kulturschichten in Südamerika" in *Zeitschrift für Ethnologie*, vol. xlv (1913) 1014-1124; Schmidt, W., and Koppers, W., "Gesellschaft und Wirtschaft der Völker" in Obermaier, H., and others, *Der Mensch aller Zeiten*, 3 vols. (Berlin 1912-24) vol. iii, pt. i; Rivers, W. H. R., *The History of Melanesian Society*, 2 vols. (Cambridge, Eng. 1914). I have not entered here upon a discussion of the views of G. Elliot Smith (see his "Primitive Man" in *British Academy, Proceedings*, vol. vii, 1915-16, 455-504, and *Migrations of Early Culture*, 2nd ed. Manchester 1929, and *Ancient Egyptians and the Origin of Civilization*, new ed. London 1923; also Perry, W. J., *The Megalithic Culture of Indonesia*, Manchester 1918, and *The Children of the Sun*, London 1923) because the basis of his hypothesis of a pan-Egyptian origin of all cultures is contradicted by all we know about primitive culture.

Culture Areas. The concept of culture areas has been developed as a device for describing the typical common characteristics of culturally related tribes. Such groups are generally found in contiguous areas, although they may also be scattered and interspersed among other cultures, like the Pygmies of Africa or the Pueblos of New Mexico and Arizona. The necessity of such a grouping develops from the bewildering variety of individual cultural forms that fill the continents. It originated in the needs of museum administration and found its first expression in the system of cataloguing introduced by Adolf Bastian in the Ethnographical Museum at Berlin. Ratzel in his *History of Mankind* based his descriptions on this device, and Clark Wissler employed it in his description of the North American Indian. Like every other classificatory device built on a selection of typical traits, the concept of culture areas contains a strong subjective element and varies according to the stress laid upon one or the other traits of culture. To those who see the principal trait of culture in economic conditions and inventions and to those who lay particular stress on psychological attitudes, folkloristic material or social organization, the culture areas will not be the same. To those who have a keen feeling for the varying associations between such elements or who stress more minute differences, large culture areas appear too generalized. The assumption that the generalized characteristics of the culture area are present in any one of the constituent social groups may give an entirely erroneous picture of the integration of cultural values in a particular tribe. Thus the classification of the agricultural tribes east of the Mississippi valley, of the western prairie tribes and of the plateau tribes who were fishermen and buffalo hunters, each into one group in which all their cultural manifestations are thrown together, would give a warped picture of the individualities of their cultural types, although it is a convenience in visualizing certain aspects of their lives. This difficulty is also manifested in the concept of marginal areas which is a necessary complement to that of culture areas, because in intermediate districts the selected typical forms lose their prominence. The marginal cultures are no less complete in themselves than the typical ones, although they do not find an adequate place in the scheme of culture areas. In exceptional cases important contrasts may be found that set off one culture against another, such as Eskimo and Indian, Pueblo and nomadic Athapaskan.

Pygmy and Bantu, but much more commonly transitional forms are found. The description of a typical tribe gives a safer insight into an integrated culture than the description of a culture area. On the other hand an analysis of culture areas as defined from various points of view, material culture, social organization and beliefs, gives us an insight into the conditions that helped to shape each individual culture.

Consult: Wissler, Clark, *The American Indian* (2nd ed. New York 1922); Herskovits, M. J., *The Cattle Complex in East Africa* (Menasha, Wis. 1926); Ankermann, B., "Kulturkreise und Kulturschichten in Afrika" in *Zeitschrift für Ethnologie*, vol. xxxvii (1905) 54-90.

Historic Reconstruction. Archaeological research and the analysis of cultural forms are the only approaches by means of which historical reconstructions can be made. In favorable cases the sequence of deposits and fullness of remains may give a clear insight into historical happenings, although there often remain doubts in regard to the direction of cultural movements. European and Oriental prehistory and partly the prehistoric investigations of the Pueblo country, Mexico, Central America and Peru show that considerable parts of local history may be cleared up and that also early relations that extend over continents may be discovered. The analytical study of modern cultures gives us first of all merely a picture of geographical distribution which must be interpreted in historic terms. When adjoining cultures are studied, the fact of diffusion can generally be discovered with satisfactory probability. When the continuity is broken, convincing proof becomes the more problematic, the simpler and the more locally confined the phenomena compared and the greater the distance between the places of occurrence. The direction of dissemination and places of origin are not easily ascertained because the place of highest development and the center of present distribution do not need to coincide with the place of origin. An example of this is the distribution of tattooing, particularly in Polynesia. Most elaborate systems are found in New Zealand and the Marquesas; but these were not the places where the art had its origin. The sledge of the Arctic need not have been invented in Siberia where the most elaborate forms occur; bronze was not invented in Scandinavia where at one period it had a remarkably high development. For these reasons the historical results of an analytical study of culture may be convincing for recent changes in narrow areas

and therefore of great value because they illustrate the kind of cultural changes that are occurring. They may even reveal the processes by means of which these changes came about. The more remote the time and the greater the distances between the areas to be compared, the more uncertain will be the results. A systematic chronological history of the sequence of cultural types the world over, although much to be desired, seems at the present time unattainable.

On the other hand negative evidence based on the presence of certain cultural features in one area, their absence in another, may give important evidence of continued separation. Universal distribution of cultural forms, if substantiated by great prehistoric antiquity, may be taken as proof that the form in question was either carried along by man as his habitat spread over the whole world, or invented repeatedly at a very early time. Stone flaking is almost universal. In a few places where hard woods offer a satisfactory substitute it does not occur. Fire is used all over the world. These have also been shown to occur in palaeolithic times. On the other hand, pottery and agriculture are not universal and they appear only in neolithic times. Metal work is restricted to the Old World and a few advanced tribes of Central and South America. Its invention is much more recent. Nevertheless universality of distribution cannot always be taken as proof of age. This can be seen in the history of Indian corn and of tobacco, which have spread all over the agricultural world since the discovery of America.

The contrast between the Old World and America indicates the early separation of the two continents. The plants on which agriculture is based in America are throughout distinct from those of the Old World, where millet was probably cultivated in gardens. Later, with the introduction of the plough, wheat and barley came in. Rice has been cultivated for a long period in eastern Asia. American agriculture is based on Indian corn, beans and squashes, all American plants. If American and Old World agriculture were historically connected we should have to expect that some of the important plants would be common to both. The American pottery area is separated from that of the Old World by one without pottery in the American Northwest. Domestication of large animals, excepting the dog, is confined in America to the Andean plateaus. Among American traps the spike trap (a ring with spikes turned inward) is absent, although it is common

in the Old World. America does not know the wheel. These differences in material culture are accompanied by others in custom and belief. America lacks an organized judicial procedure. The formal taking of evidence, the oath for the purpose of ascertaining guilt, the ordeal, are unknown in America. Even in Mexico no true ordeal is found. The idea of obsession by spirits which enter the body of the obsessed and belief in the evil eye seem foreign to America. In literary form there is an almost complete absence of the riddle and proverb. The few given by Bernadino de Sahagun (*Historia general de las cosas de Nueva España*, ed. by C. M. de Bustamente, 2 vols., Mexico 1829-30; vol. ii, p. 232-37) may be suspected as due to Spanish influence. These disagreements are much more convincing than the agreements which may be ascribed to parallel development, while the complete disappearance of essential parts of culture complexes seems very unlikely.

On the other hand, Europe and the greater part of Asia and of Africa must be considered culturally as a unit in which most of the traits absent in America have been historically disseminated: cultivated plants; animals of Asiatic origin, as the African cattle; judicial procedure with the taking of evidence, the oath and the ordeal; the abundance of riddles and proverbs; in a large portion of the Old World the ancient use of bronze with the typical fibula; the use of milk; of the wheel; of agriculture with the help of the plough drawn by animals; the belief in obsession.

Primitive Mentality. A distinction must be made between three aspects of primitive mentality. One of these relates to the mentality underlying the type of thinking and feeling expressed in primitive culture; another to the mentality of the individual as a member of primitive society; the third to that of the group. Folk psychology, as it is generally understood, deals with the first of these three aspects. Its basis must be found in the mentality of the individual as developing under social and other environmental stresses and in the forms of mental behavior of the community resulting from the joint action of the individualities formed and forming under these social stresses.

The mentality expressed in primitive culture differs from that prevailing in educated, civilized society in so far as fancied relations between the objective world and the fate of man occupy a prominent part. We call these beliefs, in so far

as they survive among ourselves, superstitions. Included in these fancied relations are those relating to the effects of man's own objective action, reacting upon human lives through their influence upon the real or imaginary objective world—so-called magical art. Notwithstanding the prominence of this aspect of primitive thought the everyday activities and the range of knowledge of primitive tribes show that under other conditions their thoughts are regulated by a clear recognition of the practical means that are required in order to attain an object. Cause and purpose are clearly recognized, both in practical everyday life and in language. The early discoveries of primitive man illustrate his ability to profit by experience and to retain what is practically useful, and the numerous activities by means of which technical or other practical difficulties are overcome prove that in practical activities he acts and plans as we do. Sometimes his work is accompanied by what we might call extraneous actions that have no immediate relation to the object to be attained, such as prayers and observance of tabus and other ritualistic acts, but psychologically there is no fundamental difference between these customs of primitive life and the customs current in our civilization of invoking church ritual in activities that claim particular social importance, such as marriage, legislative and educational meetings or war. The essential divergence lies in different concepts of helpful or hindering powers that have no true causal relation to the actions that are being performed.

The knowledge of nature possessed by primitive man is essentially practical, not systematized, although beginnings of systematization may be found in methods of measuring time and space. The control of nature is imperfect, and untoward accidents in daily pursuits are more common than in work carried through by the perfected machinery of our times. At the same time much of the labor of primitive man is far more essential, in its direct results for the maintenance of life, than in our civilization, in which this relation is felt only through the intermediary of money values. This is one of the reasons that gives a higher emotional tone to many aspects of primitive labor.

It has been pointed out before (p. 94) that the power of influencing the course of events, conceived either anthropomorphically as a will power or as a quality, is believed to be inherent in the objects of the outer world. It does not seem necessary to assume that these concepts

develop through mental processes different from our own, for the experiences of everyday life teach constantly the existence of forces that cannot be overcome and that lead by the ordinary processes of conceptualization to the opposites of normal and supernormal, that is, supernatural, power. Their influence upon human activities is constantly held in mind. Under these conditions the emotional background of life is strengthened, and similarity of emotional attitude forms an associative bond. Thus it may be understood that the principal food animals and the powers that control them may among some tribes present themselves to the mind together, as a unit and in this sense identified, like the Christian Trinity. In the same way a person may identify himself with an animal when the emotional associative bond is strong enough. The warrior who not only acts a bear, but identifies himself with a bear, does so in the particular aspects of warlike ferocity, while at other times he may identify himself with his ancestor or with his totemic animal. This identification is probably analogous to our identification of music and sound waves. The two are identical from the viewpoint of physics, and yet musical form, auditory impression and vibration of the air are distinct. Owing to lack of clarity of expression the partial identification appears as complete.

While the knowledge of nature is not systematized, it is not rare to find that the beliefs of the tribes are brought into a system, generally the more so the more they are in charge of a few or single individuals. The mythologies of the Polynesians, those of the west Africans and those of the Pueblos of New Mexico may serve as examples. Even where the unifying effect of a single mind does not make itself felt, fundamental thought patterns may be recognized that underlie the views and attitudes of the people. This difference is probably due to the lack of a unity that holds together the many scattering observations of natural phenomena, as against the single notion of supernormal power in its anthropomorphic and qualitative form that is the basis of those beliefs and actions which are not derived from the practical handling of objects.

It does not seem necessary to assume on account of these cultural viewpoints that primitive man has a type of mind different from that of civilized man. His intellect deals with the phenomena of the world in the same way as ours, but with a different knowledge which

admits what we should call supernatural interference with the laws of nature.

These considerations are not quite true for the individual in primitive society. In order to understand his way of thinking and feeling, it must be remembered that by education and imitation definite types of mental processes have been established and that a certain traditional content has been transmitted to him. With these he operates. The manner of thinking and feeling and the contents of tradition are normally not subject to critical examination. They form the basis of thought and action. A study of the behavior of primitive man shows that, given his premises, he acts logically. The acceptance of traditional premises is not a proof of a type of thought different from our own, but analogous to our acceptance of traditional theories, right or wrong. The stimulus to criticism contained in our diversified civilization and in the systematic exploration of nature does not manifest itself with equal intensity in other aspects of modern life. It is also not admissible to assume that criticism of tradition and skepticism in regard to traditional dogma never occur. Even the traditional tales of people tell of unbelievers, and individuals are found to whom the supernatural means little or nothing until they are shaken by strong emotions.

The mentality of the group finds expression in the interaction between individuals and in joint action. In so far as interaction between individuals remains in the bounds of individual behavior, it introduces new aspects into the scope of thought and feeling of the individual, but does not introduce other new elements. It is different in cases of joint action, when the close contact among the many releases the reactions of the crowd. The opportunities for expressions of crowd psychology are numerous in all societies in which joint enterprises are common. Joint hunting expeditions, migrations of the tribe from one village to another, group games, war, assemblies with much oratory and singing, group rituals, particularly those combined with dances, evoke the crowd spirit in which the emotional side of the mentality is immensely strengthened, and emphasize the emotionally conditioned associative acts.

The intellectual powers and the will power of primitive man appear different from our own when measured by the motivations characteristic of modern life. When measured by their own motivations these differences seem insignificant. In practical everyday life intelligent effort is

evident; the will power demanded in war, hunting expeditions and in the enduring of hardships imposed by custom is no less than what we find in modern life. There is greater emotional instability owing to the stress laid upon supernormal influences controlling human life and the frequency of group activities. The emotional indifference exhibited in other cases that in modern civilization evoke strong emotional reactions—like the death of infants, or cruelty—shows that there is no essential difference in capacity for control, but that the conditions for exciting strong emotions are different.

Laws of Cultural Development. The complexity of cultural development is so great, and the conditions that determine the course of historical happenings are logically so entirely unrelated, that the attempt to give an adequate explanation of the history of any individual society in regard to biological type, language and culture seems hopeless. Under favorable conditions certain specific sequences may be discovered and a strongly generalized picture of some of the fundamental facts in the history of mankind may be ascertained, such as refer to the original home of man, his gradual spread over the world, the sequence of inventions in different parts of the world and the special lines of development followed in continental areas.

The earlier hope of the discovery of a necessary sequence of cultural stages which

would hold good for all mankind has been dissipated. The question remains how far specific laws may be found that express analogous processes occurring in diverse societies. This question may be asked in regard to the biological, linguistic and cultural aspects of social life.

Universally distributed forms, if not carried by early man all over the world, may be interpreted as determined by human nature. The general anatomical, physiological and psychological traits found in all members of mankind are certainly so determined. They are, so far as they are not shared by animals, the specific characteristics of the human species. Upright position, the form of the foot, the development of the brain, the adjustability to animal and vegetable food, the functioning of nervous system and sense organs belong to this group. The most generalized traits of language are also more easily understood as due to psychological necessity rather than to divergence from an early pattern. The classification of experience and the symbolic representation of each class by articulation; the necessity of bringing these classes into relation in order to convey a meaning from person to person; the distinction between the speaker, the person addressed and the object spoken of, are unavoidable characteristics of language. In the same way general characteristics of human thought may be determined. Adolf Bastian saw the prime object of ethnological study in the discovery of these forms of thought, the *Elementargedanken* which may be discovered in every culture, diversified as *Völkergedanken* according to modifications determined by the "geographical province." The classification of experience, particularly as expressed in the separation of object and attribute and the re-objectivation of the attributes, leads immediately to generalized thought forms which, notwithstanding their diversity of form, are expressions of the same mental processes. In this class are also the universal occurrence of inventions and of the objective knowledge of the world, results of physical work; of metaphysical knowledge, due to methods of classification; of religious knowledge, based on the emotional reaction of man to the powers that control him and that he controls; of the standardization of artistic style, and of ethics. From Bastian's point of view the universality of occurrence has particular importance.

Another set of problems refers to laws

governing changes in bodily form, language and culture. The occurrence of a hereditary modification of bodily form will spread or become extinct in the population according to the laws of genetics. Linguistic forms influence one another by analogy; sounds are assimilated or dissimilated. An established cultural pattern will dominate the cultural behavior. General laws may also be discovered referring to specific relations between various aspects of social life. Here belong, in the domain of biology, those dealing with the phenomena of the influence of environment and selection upon form and function of the human body. The increase of stature under the improved hygienic conditions of modern times may be generalized and said to hold good for all populations. Similar problems present themselves in the study of language. Most of these refer to linguistic changes that occur under the stresses of cultural requirements and relate to semantic changes, or to the formation of new words or forms that meet the new needs; to suppressions and replacements due to tabus; or to the formation of metaphorical expressions.

In the discussion of the integration of culture (p. 98) a few of the phenomena that may be expressed in the form of generalizations have been mentioned. Here belong the relation between density of population and increased social regulation; the limiting effect of environment and of economic conditions; and the molding effect of a pattern developed in one domain of social life over others. These generalizations, unless qualified by an application to specific social conditions, are likely to be so vague that their value for the understanding of definite problems is not great, while the specific cases are so complex that the generalizations are no longer applicable to any considerable number of societies.

Although the doctrine of unilinear evolution can no longer be maintained, it seems possible that laws exist that determine the development of a given culture in a definite direction. The gathering of vegetable food was followed by garden culture; the use of stone by that of copper, both in the Old World and in America. The development of modern science proceeds on the whole in a definite direction. As long as the same principles of thought or action persist, general characteristics of development may be predicted. When the beauty of decorative art is seen in an abundance of lines that cover the whole background, the profuseness of decorative

motives will increase, but it can not be predicted either what particular direction decorative motives will follow or when a sudden change in taste may set in. When metaphysical or religious knowledge begins to be systematized the system will be elaborated until a new line of interest turns thought in a new direction. Probably all that can be said is that as long as a certain trend of activity or thought persists it will proceed, on the lines laid down, toward an increasing intensity or complexity. Nothing can be predicted in regard to detailed style of development, the duration of the trend and the new direction that action and thought may take after its termination.

FRANZ BOAS

See: ARCHAEOLOGY; ANTHROPOMETRY; CULTURAL GEOGRAPHY; HUMAN GEOGRAPHY; PREHISTORY; CULTURE; CIVILIZATION; LANGUAGE; RACE; MAN. *See* also articles on specific anthropological topics discussed above.

ANTHROPOMETRY may be defined as the measurement of human beings. The term is synonymous with physical anthropology and is an integral part of biometrics, since its data, in large measure, are to be understood only through the use of statistics. The two types of anthropometric measurements gathered are those which are taken on the living and those taken on the skeleton.

Measurements which can be taken on the human form are almost infinite in number, but they have been standardized by anthropologists so that not more than one hundred are utilized. Indeed in actual practise far fewer are considered, and generally too few measurements are taken. Those favored most are head length and breadth, auricular head height, facial height and breadth, nasal height and width, stature, height sitting and bodily proportions, from which various indices are derived. Non-measurable traits such as color of hair, eyes and skin, the form of the hair, the presence or absence of the epicanthic eye-fold, the degree of prognathism, are also noted. In addition traits such as cranial capacity, total height of the head, and measurements of the long bones are usually taken on skeletal material. The most complete

set of measurements is that of Martin's *Beobachtungsblatt*, where provision is made for practically all measurements on the skeleton and the soft tissues, for observations of non-measurable traits and for indices derived from the measurements.

One of the anthropologist's important problems is that of guarding against sources of error. The first is that due to the personal factor present in measuring. Another is that arising from the instrumentarium used. Some instruments, such as the spreading and sliding calipers, are of great accuracy, but others, such as the older radiometer, had large observational error. The third source of error is that of the conditions under which measuring is carried on. Thus, in a study of growth, it is important to realize that there is daily variation in stature which might conceivably affect the results. More serious are the errors entailed in the fact that landmarks used in taking many measurements on the living are obscure, due to the soft tissue over the subcutaneous bony structure. On the other hand there is a tendency on the part of some to insist on what may be termed spurious accuracy in measurements, which goes with a failure to realize that a small error in a large measurement need not be significant and that measurements are not to be regarded as ends in themselves.

The relation of the traits measured to the purposes of the study for which they are measured is a point which has been grievously missed. Tremendous emphasis has been placed on the measurement of head length and breadth, and populations have been placed in racial categories mainly on the basis of these traits, with perhaps a correlated series of observations of skin color, stature and color of hair and eyes. It must be obvious, however, that difference in head form is only one of an almost infinite set of differences which may be found between any two peoples, and it has happened too often that other important traits have been omitted. The problem of racial differences, especially in the differences between the European subtypes, has been considered practically solved when differences in head form and stature and color of skin and hair have been shown to exist, and the further fallacy has occurred of then attributing other characteristics to these "types," such as psychological traits. An example of this is a recent study of the "racial" incidence of cancer in Europe which was attacked by correlating numbers of cases in given districts with cephalic index and stature. The feeling at the present

is that the traits which should be measured are those which fit the problem in hand and, as a rule of thumb, that the more numerous the traits measured, the greater the validity of results obtained from the study, other things being equal. Thus, in a study of differences between long headed north and broad headed central Europeans, the form of the head would be of considerable importance, while in a study of the differences between long headed north and long headed south Europeans, head form would be of very little significance. As a matter of fact the classificatory method is being discarded for the more empirical one of studying a given group in an endeavor to describe it as it is and to understand the processes involved in its formation, rather than to make it fit into more or less arbitrary schemes of classifications. Among the earliest work of this type was that of Franz Boas, who studied the influence of change of environment on physical form, and of Eugen Fischer, who studied the south African Bastards to obtain insight into the processes of human race crossing.

It is only seldom, as in the cases of prehistoric finds, that measurements on one individual are undertaken, but here they are of major significance. The data of anthropometry are generally such that statistical treatment must be given the material gathered. There are certain anthropologists, however, notably Hrdlička, who feel that statistical handling of results befores them. Students who follow this opinion are for the most part more interested in problems of morphology than in those of a larger social nature which anthropometry may help to solve, and in the United States and England they are in the minority. On the continent most anthropometric work is of this nature, and it is only recently that the importance of statistical handling of mass data has been realized. Statistical analysis of physical measurements characterizes the work of most American anthropologists, such as Boas, Todd, Hooton and others. This group feels that the element of selection is highly important and that only recognition of the laws of chance will tell whether the results of a study are representative.

The most important problem to be studied is the differentiation of human groups, both the larger ones termed races, and the smaller groups which have become dissimilar in physical form. This was the first work done by anthropologists, and today we have not inconsiderable data on the basis of which the races of man and

the subtypes within them can be distinguished. Much attention in earlier times was given also to criminal anthropometry, but interest in this phase of the work has today largely lapsed. Then came the problems involved in racial crossing: problems of great social significance such as the results of race crossing and its desirability or undesirability. The processes of human heredity, to the consideration of which Boas, Davenport, Lundborg, Fischer and others have outstandingly contributed, pose the next large group of problems. Whether Mendelian heredity in its simpler forms is operative among human beings has yet to be solved by the anthropologists, but its social importance for a knowledge of human behavior as influenced by the crossing of different peoples is obvious. The fact that man is a slow breeding animal makes the study of human inheritance a matter for involved statistical treatment, and makes it necessary that material should be gathered from large numbers of parents and their children.

The effect of social conditions on growth is another problem which the anthropometrist is attempting to solve. The work of Baldwin, Boas, Martin, Todd and others stands out in this line. The establishment of criteria of physiological as against chronological age is involved in this, and measurements of the bones of the hand, wrist and forearm in children, as shown on radiographs, constitute one recent method of attacking the problem. Differential rates of growth in different environmental conditions, holding the racial factor constant, involve another type of problem which anthropometrists have attempted to solve, a problem to the understanding of which the research of Martin on the German "famine-children" greatly contributed. Repeated measurements on the same children are also being stressed; the feeling being that we have sufficient mass data on growth to go as far as such material will allow, and that intensive study of the same individuals will yield enlightening information which will again give new leads for further research. The problem of heredity versus environment is the last great problem which faces the anthropometrist. That man is a flexible organism seems established, and the problem resolves itself into determining the limits beyond which adaptation is not possible. Bauer's concepts of idio-variations and para-variations have helped to clarify the problem, and further measurements under what simulates control conditions may in time bring

a solution of this puzzling and important question.

ANTICLERICALISM is the term applied to the movement peculiar to Latin Catholic countries that aimed to free politics from intervention by the clergy and to establish the supremacy of the lay state over all religions. Indirectly anticlericalism was a result of the Protestant Revolution which, wherever it succeeded, subordinated the church, in doctrine as well as government, to the control of civil authorities. Even those countries that remained Catholic submitted no longer to the church in civil matters as they had done during the Middle Ages. By a system of agreements, known as "concordats," between the Catholic kings and the pope, the former managed to obtain a definite recognition of their claims to nominate bishops and to regulate church taxes.

In Catholic countries the church had so many privileges, judicial, financial, educational, that it was almost a separate body; the government merely had some rights in its affairs. When absolute monarchy finally managed to establish itself, however, a movement began in these countries to subject the church to royal control. In France it was known as "Gallicanism." It failed because the Catholic masses were "ultramontane" and regarded the pope, not the king, as the supreme ruler of the church. The French Revolution is as important in religious as in secular history. The *philosophes*

who inspired its ideals were animated by a bitter hatred of Catholicism, and with the revolution a struggle began between church and state that resulted in confiscations, suppressions, proscriptions and finally separation. When Napoleon assumed power he entered into an agreement with the pope, the famous Concordat of 1801, which reestablished the church but completely subordinated it to the government. Gallicanism was now triumphant.

"Clericalism" and "anticlericalism" first appeared during the Restoration, though the terms were not commonly used until the sixties of the nineteenth century. Anticlericalism originated in France, where its ideas were most clearly formulated and its policies most persistently followed. It is therefore the movement in that country that will be considered here. The anticlericalism of Italy, Spain and Portugal was to a large extent inspired by that of France.

In France the restored Bourbons maintained the Concordat because they were loath to lose the control over the church that it provided, but they did everything in their power to encourage the spread of Catholicism. They relied upon the church to counteract the influence of the French Revolution. In parliament the Bourbons were supported by the "clericals," known as the *parti prêtre*, who put through a number of laws in the interest of the church, the most notable being the Sacrilege Law (1826) which punished with death the profanation of holy vessels under certain circumstances. The country was greatly aroused, and an anticlerical sentiment grew up bitterly hostile to the alliance between Bourbonism and Catholicism. The anticlericals proclaimed the doctrine of the lay state (*l'état laïque*), favoring separation of church and state, civil marriage, divorce and secular education. They were generally known as *libres penseurs* because they rejected the authoritarian spirit of Catholic teaching.

Throughout the history of nineteenth century France the opposition to absolutism was animated by the spirit of anticlericalism. It was the one bond of union between constitutional monarchists and republicans during the first half of the century, and between radicals and socialists during the second half. The famous secret societies, the *charbonnerie* (similar to the Carbonari) and the Free Masons, were also active in fomenting opposition to clerical governments. Catholicism was not, however, in the first half of the century considered

synonymous with clericalism, and there were Catholic anticlericals, like Royer-Collard and Montlosier, Gallicans in religion and liberals in politics, who bitterly criticized the clerical policies of the Bourbons as a violation of the spirit of the Concordat. More radical in their anticlericalism were those who inherited the deistic traditions of the eighteenth century, like the historians Michelet and Quinet and the philosopher Jules Simon, who sought to isolate the church from all contact with public life. At the extreme left of the movement were those who, like the socialist Blanqui and the anarchist Proudhon, inherited the Jacobin tradition of war to the death against the church; in their view there was a fundamental incompatibility between the Catholic church and the French Revolution, the one authoritarian, the other libertarian, in spirit. The anticlericals of that period seldom advocated the separation of church and state, though in theory they favored it. So influential was the church that they feared to set free the "one power in France which does not emanate from the central government" (Simon).

Anticlericalism found its chief supporters among the bourgeois, who opposed the church as the protagonist of aristocracy and royalism. With the growth of revolutionary socialism among the working class, however, the bourgeois turned to the church as the bulwark of social conservatism. It was believed that the teaching of religion would inspire among the poor a respect for the institution of private property. Thiers, the representative of the freethinking bourgeois, frankly admitted that the priest was "an indispensable rectifier of the ideas of the people." Largely through his influence the *loi Falloux* was passed (1850), which in effect gave to the clergy the control of primary and secondary education.

During the latter half of the nineteenth century anticlericalism underwent a marked change. It became definitely anti-Catholic, which, in France, meant anti-Christian. The papal encyclical, *Quanta cura*, and the *Syllabus of Modern Errors* had the effect of convincing moderate anticlericals that no distinction could be made between Catholicism and clericalism. Another influence was the advent of the Marxian socialists whose materialistic philosophy was opposed to religion. After 1850 the socialists regarded the church as the protector of bourgeois society, and they were consequently its uncompromising enemies.

The greatest battle between clericals and anticlericals occurred during 1871-79, the critical period in the history of the Third French Republic when royalists and republicans struggled for control. The church supported the royalists so ardently that "Catholic" and "royalist" became synonymous terms. In opposition were the republicans led by Gambetta, whose famous cry, "Le cléricalisme, voilà l'ennemi," roused all France. Anticlerical journals appeared, notably *Dix-neuvième siècle*, edited by the brilliant journalists About and Sarcey, that denounced and ridiculed the church in true Voltairean fashion. The Third Republic and the church were soon engaged in bitter conflict. The Ferry laws (1881-82) established a national system of free, secular, primary education which encountered the uncompromising opposition of the church. Divorce was instituted in 1884.

But the anticlerical republicans paused before the more serious step of separating church and state. They had come into power chiefly as a result of division among the royalists, and they feared that a move toward separation might lead to the overthrow of the republic by an aroused Catholic sentiment. The question came to the front several decades later during the Dreyfus affair, when the royalist-clerical combination again menaced the republic. During this crisis the radicals and socialists formed a Republican bloc that put through the most famous anticlerical laws in the history of France, the Association Law of 1901, which resulted in suppressing nearly all the Catholic orders in France, and the Separation Law of 1905, which separated church and state. These laws were the work of the anticlerical ministers Waldeck-Rousseau, Combes, Clemenceau and Briand. In the Chamber they had the powerful support of the socialist statesman-orator Jaurès. Bourgeois radicals and proletarian socialists were now in alliance against the church because they had a common interest in maintaining a democratic republic.

Anticlericalism became an "extinct volcano" after the Separation Law. The radicals were left without their chief issue, and the socialists had cleared the ground of the religious question which had distracted the nation from the more important social question. During the World War Catholics and anticlericals forgot their religious differences in their common hatred of the German invaders. After the war the fear of clericalism had so far subsided that the

republic reestablished relations with the Vatican and modified certain clauses in the Separation Law in deference to the wishes of the church. During the Herriot ministry (1924-25), which was supported by a bloc of radicals and socialists, anticlericalism again flamed forth in the attempt to apply the secular education laws to the schools of Alsace-Lorraine. But the attempt failed, as there was no desire to revive an issue that would distract France from post-war problems.

ANTI-CORN LAW LEAGUE. Long before the formation of the league which brought about the abolition of the Corn Laws there had been steady if not systematic agitation against these statutes. In the course of years absolute import prohibition had been abandoned and later sliding scales of duties had been introduced as palliatives for increasingly intolerable conditions, while in famine time the ports were opened. The league was unique in being the first powerful organization whose efforts were concentrated on repeal, complete and permanent. For some time events had been forcing the government to face a reorientation of fiscal policy. The impetus came chiefly from the continued distress of the laboring class, kept at a low standard of living by the dearth of a staple foodstuff, the periodical dearths which intensified suffering and discontent, the growth of population, the expansion of industry, particularly in the North, and the need for larger foreign markets. What had been lacking hitherto were minds and wills capable of coordinating the forces which were making for reform and using them as weapons in a great offensive movement against land monopolists and their privileges.

The league had been preceded by the Anti-Corn Law Association, formed in London in 1837. That body, however, consisted less of practical men than of theorists, and its policy did not go beyond a reduction of the existing duties. Such a concession could not meet the needs of the industrial North, and accordingly the Manchester Chamber of Commerce took up the question in December, 1838. Richard Cobden, then a manufacturer of the city, stood for complete repeal and obtained the adoption of his plan. So in January, 1839, was formed the National Anti-Corn Law League for promoting the total and immediate abolition of the duties. The league lost no time in setting in motion a powerful mechanism of propaganda, adopting as its organ a sheet called *The Anti-Bread Tax Circular*, which later gave place to *The League*. The effective arena of agitation, however, consisted of the House of Commons, the political platform, the public press and the pamphlet. Of this agitation Cobden was the director, although many able and devoted colleagues joined him, notably John Bright.

The task which the league had to face was not only to convert a nation but to overturn enormously powerful interests which had long controlled both the electorate and the legislature. Branches of the society were formed in all parts of the country. Trained lecturers were poured into the industrial towns, the rural villages and the open countryside, and as many as a million tracts and other publications were distributed in a single year. Money flowed in freely, and on one occasion a fighting fund of £250,000 was raised. Throughout the agitation the men of the "Manchester school" had to encounter gross misrepresentation and obloquy. They were reviled as bagmen and egoists who exploited the toilers of the factory and mine and preached philanthropy for profit. But these tactics failed of their purpose, and the time came (1843) when even the *Times*, the mouth-piece of the classes, which had begun by ignoring and continued by abusing the league, ended by proclaiming that it must be accepted as "a great fact."

Meanwhile Peel had come to power in 1841, the head of a Tory-protectionist ministry and party, and in the following year he introduced a new sliding scale. Nevertheless he was wavering, for at heart he was a Whig and the Whigs were rapidly coming over to repeal. His formal capitulation came in January, 1846. The three traditional allies of reform—famine, distress and

disaffection—once again fought on the side of repeal. Something had to be done, and instead of playing any longer with emergency measures he determined to end, instead of mend, a hopelessly unsatisfactory system. Accordingly he introduced a bill for total repeal, to come into operation on February 1, 1849, and a moderate sliding scale to continue until that date. The measure became law without encountering serious opposition. In the House of Commons nearly all the Whigs and over a hundred of the Tories voted with the majority. Simultaneously the duties on many other articles—food, farm produce, raw materials and manufactured goods—were either repealed or reduced, and the Navigation Laws were also abandoned.

ANTIMILITARISM is the theory and practise of the struggle against militarism conceived as a policy of the modern state carried out through the institutions centering around the army and navy. The term has been applied at the one extreme to a mild advocacy of a retardation in the race for armaments and at the other to agitation for a general strike against war. It is therefore not identical with pacifism, although some of the more radical groups of pacifists share views akin to those of outspoken antimilitarists, but is more definitely related to anticapitalism. Antimilitaristic ideas were first openly and clearly discussed at the congresses of the First and Second Internationals, and some socialists, e.g. Karl Liebknecht, carried on an active antimilitarist propaganda before 1914. But as a coherent theory and concerted movement antimilitarism results from the writings and work of the anarchists and of the revolutionary syndicalists. It was the French Confederation of Labor, under the special influence of such anarchists as George Yvetot and Émile Pouget, which after 1900 started in the French army a vigorous campaign for gen-

eral strikes and military insurrections as a means of preventing war. The French Confederation of Labor created the *Sou du Soldat*, for the purpose of giving economic aid to soldiers in the army and maintaining contacts between trade unions and conscripted trade union members. In 1901 the confederation published an antimilitaristic tract under the title *Manuel du soldat*, which went through many editions.

At present there are three main varieties of the antimilitaristic movement. Socialists and such international labor organizations as the "Amsterdam" International carry on propaganda against war and in favor of immediate steps toward general disarmament. Their point of view is that militarism and war are inevitable results of competitive capitalism and can disappear only with the triumph of socialism. Certain of the organizations under socialist influence, especially the socialist youth societies, encourage their members in some countries to pledge themselves to refuse military service in case of war.

The most outspoken and vigorous opponents of militarism today, as before the World War, are the anarchists and the syndicalists. From their point of view, war is not only a horrible result of capitalism but an inherent element of the state which claims the monopoly of the right to kill. Anarchistic and syndicalistic propaganda today, as before the war, centers around the ideas of the general strike and of military insurrections as means of defeating war. In most countries the followers of these doctrines evade military service and stir up discontent among military recruits. For purposes of propaganda and agitation the syndicalists and anarchists maintain the International Anti-Militarist Commission with headquarters at The Hague, Holland.

An intermediate place between the socialists and anarchists is held by the communists. While agreeing with the anarchists that the ultimate ideal of society is one from which the state and all military organizations have disappeared, the communists emphasize the importance of the transitional stage of the "dictatorship of the proletariat," during which the workers as a ruling class will have to maintain an army for self-defense. For the immediate future the communists elaborate the idea of a "socialist fatherland," which is Russia, and insist upon the necessity of gaining influence in the armies of the "capitalist" countries in order to prepare for the social revolution.

Their aim is thus not so much to disorganize existing armies as to "capture" them, and for this purpose communists are exhorted to organize cells and nuclei in the army, navy and all other military institutions. Communist antimilitarist activities are especially widespread at the present time in France and in England.

LEWIS L. LORWIN

See: PACIFISM; PEACE MOVEMENTS; SOCIALIST PARTIES; SYNDICALISM; YOUTH MOVEMENTS; GENERAL STRIKE.

Consult: Levine, Louis (Lorwin, Lewis L.), *Syndicalism in France* (2nd ed. New York 1914); Lorwin, Lewis L., *Labor and Internationalism* (New York 1929).

ANTIRADICALISM. In its most general sense this term covers all sentiment and action aiming at the suppression of agitation or doctrine regarded as subversive of existing institutions. Antiradicalism commonly conceives of itself as allied to the state, but when the latter has been captured by the radicals, as in the case of the French and the Russian revolutions, the anti-radicals compose a counter-revolutionary movement seeking to reestablish the institutions overthrown by revolution.

As the institutions subject to radical attack vary with time and place, so also do the objectives of antiradical movements. The specific objective of antiradicalism in early modern times was the defense of the church against heresy; through the eighteenth and the early part of the nineteenth centuries antiradicalism was occupied with the defense of monarchical and aristocratic political institutions. Defense of the institution of private property has been the predominant element in recent antiradicalism. Other elements, however, enter into the complex: defense of the church and religion, of traditional family institutions, of established political and juristic forms, of conventions in morals and manners, even of the traditional canons of art and letters.

In ordinary times antiradicalism is implicit in the attitudes of various social groups, but does not work itself out into a consciously formulated body of principles and rules of action. The heretic or the political or economic "dreamer" is ridiculed, ostracized, occasionally expelled from the community, but no extensive mass emotional disturbances are involved. The situation changes entirely when radicalism develops to the point of becoming a serious challenge to existing institutions, as in times of prolonged economic depression, during or after an exhausting war or in a period of rapid economic

development which effects serious changes in the distribution of wealth. In such circumstances implicit antiradicalism awakens into self-consciousness and may develop into a general panic. In Russia the political radicalism which flourished after the Russo-Japanese War evoked a powerful antiradical reaction which drew into its circle extensive groups of the population, as, for example, the class of small traders and peasants, whose only animating interest was aversion to all change. After the World War and the Russian Revolution economic radicalism became a factor of importance throughout the world. It was attended, naturally, by an equally extensive development of antiradicalism.

At the outset of an antiradicalism movement the issues are usually definite and leadership is in the hands of those whose interests are actually involved. When heresy first became a problem in early modern times its suppression was left to the church; only after a long period of propaganda was the work of suppression taken over by the congregations. The suppression of abolitionist tendencies in the South was at first undertaken by the slave holders; only after decades did they succeed in animating the non-slaveholding townsmen and small farmers with a hatred of the abolitionists as enemies of the existing order. Post-war radicalism, with its attack upon an institution so general as private property, naturally aroused against itself especially those to whom private property bears a quasi-sacred character—the small merchants and manufacturers, the farmers, investors in safe securities, officials and employees enjoying security of tenure. While the dominant capitalist class contributed resources for the attack on radicalism, post-war antiradicalism was essentially a middle class movement.

All antiradicalism movements derive their force ultimately from the classes whose status has been fixed for a time sufficiently long to have lent them a certain moral quality. While the newly enriched or ennobled may fight radicalism out of naked self-interest, those who hold a hereditary property or status have as a rule assimilated it to the body of natural rights; when it is attacked they are capable of developing a high degree of moral energy in its defense. Hence the paradoxical fact that in the struggle against radicalism it is most often the classes of modest fortune—often classes of waning fortune—that are most zealous in the repression of proponents of change. The Fascist movement in Italy, the dictatorships in Spain and Hungary, drew their

essential support from the small bourgeoisie, just as antiradicalism in America is strongest among the smaller business men who are struggling to hold their own against the encroachment of the great aggregations of capital in trade and industry.

Post-war antiradicalism has been distinguished by the extensive application of the arts of propaganda developed during the war. By the wide circulation of leaflets and pamphlets, by tendential articles in the magazines and daily press, by conferences and lectures, the menace of radicalism has been brought home to the potentially antiradical masses. Emphasis has been laid upon the alleged relation between economic radicalism and heterodox attitudes in respect to other moral values. A professional leadership has arisen, skilled in creating a sense of panic and exploiting it to the leaders' advantage.

In the end an antiradicalism movement loses its momentum chiefly through the flagging of the moral energy it has evoked. The antiradical masses grow weary of hearing of menaces which are not realized in action. What at first gives force to the movement, the assimilation to radicalism of a wide range of attitudes having no direct bearing on the problem, tends finally to bring on disillusionment. While the recent movement was gathering strength it was no doubt helped along by the propagandist identification of industrial unionism, pacifism, social insurance, agrarianism with economic radicalism. In the later phases of the movement this massing together of unrelated phenomena has operated to break down the credulity of the antiradical rank and file.

Like any social-political movement which draws heavily upon moral energies and avails itself of fears and suspicion, antiradicalism makes frequent application of violent means. Lynching, deportation, flogging are frequently resorted to by antiradicalism in countries without a well established tradition of legality, such as the United States, Italy, China, the Balkan states. Blacklisting and boycotting are freely employed. Often the governments are forced by the fervor of antiradical public opinion to enact laws for the suppression of radical activities which become dead letters when the movement loses force. More frequently the public authorities—especially the local authorities—are drawn into cooperation with unofficial bodies in the lawless suppression of radical or allegedly radical activities.

The chief interest for political science in anti-radicalism lies in the evidence it affords of the failure of the modern state to develop into a true polity. Antiradical behavior proves that even those classes which are generally assumed to be most loyal to the state and the institutions which it defends are prepared at any time when their emotions are aroused to abandon the political and legal means supplied by the state and revert to force and violence.

ANTI-SALOON LEAGUE. This organization, "The Church in Action against the Saloon," is a league of churches and temperance societies growing out of the Ohio Anti-Saloon League, which was organized at Oberlin, Ohio, May 24, 1893, under the leadership of the Rev. H. H. Russell, of Berea. The success of the Ohio league led to the establishment of similar organizations in other states, and in December, 1895, at a convention of forty-nine separate temperance and religious groups in Washington, D. C., the Anti-Saloon League of America was formed. The object of the organization, as stated in its constitution, is "the extermination of the beverage liquor traffic," although the name Anti-Saloon League was adopted to direct attention primarily to the evil of the open saloon.

Stated briefly, the distinguishing features of the organization are: active cooperation of the churches, with the individual congregation constituting the basic unit, comparable to the

precinct organization of the regular parties; paid professional officers and workers under centralized control; a financial system which is based on monthly subscriptions; a program of widespread education and propaganda; concentration upon the liquor question—refusal to be sidetracked by any other issues; political agitation directed toward the defeat of "wet" and the election of "dry" candidates; legislative lobbying in behalf of restrictive legislation and a constant demand for adequate enforcement.

The Protestant evangelical churches have always constituted the backbone of the league. During its campaign for national prohibition, 1912-1918, upwards of 50,000 churches regularly threw their pulpits open to Anti-Saloon League speakers of which there were at times as many as 20,000 in the field. In Pennsylvania alone more than 5000 churches cooperated.

Theoretically democratic in structure, the organization in fact has always been controlled by the small group of officials comprising the national executive committee and national board of directors, the personnel of which has changed but slightly in twenty years. The national board of directors is composed of two representatives from each state league, with additional members for states with over a million population. The real governing authority resides in an executive committee of nineteen members chosen biennially by the board of directors. A general superintendent appointed by the board of directors nominates state superintendents and has general supervision over both national and state leagues. Within each state there is a board of trustees representing the various churches. State superintendents are appointed by the local boards upon nomination by the general superintendent. Local ad hoc committees are formed from time to time. Each state league and the national organization employs a legislative agent and attorney who aids the state superintendent as political lobbyist.

Funds are secured through an elaborate pledge system. From 1912 to 1923 over \$16,000,000 was pledged to the national league alone, and in the years 1915 to 1917 the league, in all its branches, was spending about \$2,500,000 annually. Except for a few large contributions, the overwhelming bulk of the income is paid in small sums varying from a few cents to several hundred dollars. The number of contributors in 1922 was estimated at 700,000. Between 80 and 90 percent comes

in as the result of direct appeals to church congregations.

The league is primarily a propagandist agency, and for carrying on this work it maintains a thoroughly modern printing establishment, the American Issue Publishing Company, at Westerville, Ohio. From October, 1909, to January, 1923, this company turned out 157,314,642 copies of temperance papers. In addition a total of 244,782,296 books, pamphlets, leaflets, window cards, etc., were printed and circulated. Literature was distributed through the mails to a regular subscription list of over 500,000 as well as through the churches, schools and temperance societies. Through the cooperation of many large industrial concerns league leaflets were placed in the pay envelopes of the workers.

During the early days the league trained its guns on the saloon, going so far as to disavow any desire for complete prohibition. Its literature, however, made no such distinction but depicted the entire liquor traffic as the enemy of society, the home, the individual, the church, law, order and humanity. During the war it capitalized heavily on the fact that many brewers and liquor dealers bore German names and that large quantities of foodstuffs were being wasted in the manufacture of liquor. Unlike the Prohibition party the Anti-Saloon League rarely places a candidate of its own in the field. The constitution of the organization, moreover, pledges it to "avoid affiliation with any political party as such." Its object has always been to hold the balance of power, throwing its support to the candidate most satisfactorily answering its questionnaire. The league has always been indifferent to other issues and party labels. In the South it has consistently supported dry Democrats and in New England dry Republicans.

League lobbying is of a piece with tactics employed by other political pressure groups. Special legislative agents are employed to appear before committees, cooperate with representatives in drafting legislation, keep the local organizations informed as to the conduct of public officials, and to add that personal touch in matters of law making which experienced lobbyists know to be of incalculable value. The national and state leagues organize delegations to wait upon politicians and office holders, from city councils to congresses, from policemen to presidents. When antiliquor legislation is pending, they supervise the sending of memo-

rials, petitions, letters and telegrams appealing for favorable action and threatening political reprisals if the legislator fails to heed. So powerful did the league become in the national Congress that in 1917 President Wilson made a formal request in writing for its support of food control legislation then pending. The legislative program of the league began with local option for college towns, followed successively by demands for county option, state wide prohibition, the regulation of interstate liquor shipments and, finally, national prohibition. The bulk of our temperance laws were not only enacted under pressure from the Anti-Saloon League but, in a considerable number of cases, were actually drafted by league attorneys and agents. The Webb-Kenyon Act, the Eighteenth Amendment and the Volstead Act are instances.

The Anti-Saloon League does not usually take a direct part in the enforcement of liquor laws. Its activities in this connection are confined to recommending for appointment persons friendly to the law, electing public officers pledged to rigorous enforcement, strengthening existing laws, procuring adequate appropriations for enforcement, exposing inefficiency in enforcement, and counteracting agitations for a relaxation of existing laws.

Since 1926 the league has been turning its attention increasingly to the problem of educating the public concerning the evils of alcoholic beverages *per se* and the danger of wholesale disrespect for law. It has recently been given some \$500,000 for this purpose, and it has created a department of education to direct the work.

ANTISEMITISM. In its concrete meaning the word is synonymous with anti-Judaism and denotes social and political agitation, sentiments and acts directed against Jews. The term is only fifty years old, having been put into circulation by Wilhelm Marr in 1879, and has specific reference to a doctrine of race which was intended to be the theoretical justification for modern anti-Judaism. It involves the assumption that the cultural and social group differ-

ences between the Jews and the peoples among whom they reside are to be viewed as an antithesis of Semitic and Aryan racial characters, and that the Aryan peoples form a superior group which needs to protect itself against cultural and racial contamination by the inferior Semitic Jews. Were antisemitism nothing but a doctrine of race it would long ago have been discarded as a scientific superstition. But the doctrine is simply the reflection of an underlying situation which is very important both on its own account and for its bearing on many other political and social problems. Anti-Judaism (to call the phenomenon by its true name) is a reality and a fact even if the racial theory of antisemitism be dismissed as a figment of the imagination.

For an impartial understanding of antisemitism it is of course necessary not only to put aside the antisemitic theory of race (except as part of the phenomenon to be studied) but also to guard against any one-sided approach to the problem. One must, in other words, study not the "Jewish problem" but the joint problem of Jewish-Christian relations.

We are accustomed to regard the Jewish-Christian antithesis as a religious antithesis, and we accept as a matter of fact the mediaeval history of Jewish persecutions and Jewish disabilities. But with the growth of toleration in modern times and the general waning of interest in religious issues one might suppose that the Jewish-Christian problem would gradually disappear. It is on this assumption that the states of western Europe put through the program of the civil emancipation of the Jews during the eighteenth and nineteenth centuries. This assumption continues to guide most of the states of the world, and even today in Germany, a country which is the fountainhead of the antisemitic movement and philosophy, the state as a state does not recognize a Jewish problem or a Jewish-Christian problem. It is only the antisemitic parties and groups which seek to alter the present political status and to repeal, or to mitigate as far as possible, the Jewish emancipation laws.

Correct as may be this political assumption, one must dissociate from it the philosophy of social optimism which generally goes with it. To the thinkers of the seventeenth and eighteenth centuries who fought so nobly for political equality and the rights of the citizen, the emergence of the social and class struggles of the nineteenth century would have appeared as the

defeat of all their highest aspirations. Nevertheless the eighteenth century conquest of liberty may be accepted as a sound achievement, even though we now appreciate how formal and abstract in many concrete social situations political liberty really is. So, too, with antisemitism. The recognition of the social reality of a Jewish-Christian problem does not necessarily impugn the validity of the political principles of the emancipation movement.

In the face of the strong revival of anti-Jewish agitation in the second half of the nineteenth century, the purely religious interpretation of the Jewish-Christian group conflict is seen to be manifestly inadequate. Certainly the Jewish-Christian opposition is not an opposition of religion in the same sense in which the opposition between the various Protestant sects, or even between Protestantism and Catholicism, may be regarded as an opposition of religious doctrine. In the examples mentioned the conflict disappears as soon as the religious issue wanes—unless, as is the case with the Catholic situation in certain countries, the religious controversy cloaks or produces a deeper social opposition. Tragically important as has been the role assigned to the Jew in the Christian gospel and the Christian philosophy of history, the underlying sociological factors were even more important in creating the Jewish problem, both before and after the spread of Christianity. In the Roman Empire the Jews were often gravely discriminated against, even persecuted, as aliens whose devotion to their religion and ritual made complete assimilation with Roman culture an impossibility. When Christianity came upon the scene, their peculiar position as an internationally scattered minority was confirmed.

It is not necessary to review the whole mediaeval history of the Jews, but merely to recall a few incidents which produced more or less lasting social effects. Chief among these were the enactment of laws forbidding the Jews to own land and their consequent restriction to mercantile pursuits and the lending of money. The Jews were not the only traders or usurers but, as an alien element and as the people who crucified Christ, they were made the target of a peculiar combination of economic class hatred, religious passion and distrust of the stranger which has never been equaled in all history. Add to this the hermetical social isolation of the Jews in the ghetto, and one begins to understand the magnitude of the Jewish-Christian

gulf which the mediaeval period has passed on to modern times.

The moral charges and countercharges exchanged between the Jews and Christians do not concern us here. From a sociological point of view these ethical judgments, which may be true or false when each is considered in and for itself, are all absorbed in the underlying sociological determinism. More significant than these moral economic charges is the blood ritual accusation, which affects the Jews not as an economic class but as an ethnic and religious community. This charge, continuing down to recent times—the most recent examples being the Tisza-Eszlar affair in 1878, the Xanten accusation in 1891 and the Mendel Beiliss case in 1912—most truly reflects the strangeness and ignorance characterizing the mediaeval Christian view of the Jewish community. The ritual murder accusation was first leveled by the Romans against the Christians, and even today in China, whenever a Chinese child disappears, the common people believe that he has been kidnaped by a Christian missionary and his eyes extracted for use in Christian magic. The charge was not made against the Jews until the eleventh century, but from that time on there has been a long and dismal record of such incidents—an amazing example of the persistence of human ignorance and superstition.

If there has been a change in the Jewish-Christian situation since the Middle Ages, it is due to modern economic and political forces. The evolution of the secular state has made it possible to regard Jews as citizens and not as aliens kept alive as witnesses to the historicity of Christianity. On the other hand the passage from an agricultural state regulated by the canonist view of economics to the modern capitalist and industrial state has made it possible to absorb the Jews as ordinary individuals in the economic machine. Many of their presumably capitalistic virtues even came to be admired by their Christian neighbors. Neither the political nor the economic forces have affected all countries equally, and even where they have had fullest play, as in Anglo-Saxon countries, they have not completely broken up the heritage of mediaeval traditions, especially among those groups which themselves represent the survivals of an agricultural-handicraft society in an economy of full blown capitalism.

The norm and archetype of modern antisemitism is to be found in Germany. Further

east are to be found more of the physical excesses and legal discriminations characteristic of the Middle Ages. Further west antisemitism becomes a more sporadic and fugitive phenomenon, if it does not disappear entirely. In Germany antisemitism, in its peculiarly modern sense, has been developed as a philosophy and as a political movement; there it was even launched as an international movement with international congresses and representatives from Austria-Hungary and other countries.

It is customary to date modern antisemitism in Germany from the period of 1870. The date is of course significant. It was not until the unification of the German Empire that Jewish emancipation was completed and all existing restrictions on the basis of religion were abolished. These reforms marked the end of religious antisemitism—that is to say, of that antisemitism where religious application formed the basis of legal discrimination. But so little did the abolition of religious disabilities affect the underlying social situation that we find the phenomenon of antisemitism breaking out in a new form and even with increased vigor. In a sense it may be said that the same train of ideas which brought about the Jewish emancipation (and the theoretical abolition of antisemitism) actually promoted the real development of the new antisemitism. Liberalism brought with it the granting of full equality to Jews, but it also facilitated the passage of Germany into the stage of vigorously developing capitalism, the brunt of the transformation falling on the handicraftsmen and peasants, while the Jews appeared to be in the vanguard of the new capitalistic bourgeoisie. The conflict of economic forces thus engendered was but one of the factors fostering anti-Jewish feeling. In addition antisemitism drew sustenance from the repugnance which middle class morality entertained for the financial excesses of capitalism and for advanced radicalism, with both of which the Jews as a group were identified in loose thinking because of the prominence of individual Jews.

In the Germany of the 1870's socialism had not as yet been declared to be Jewish in origin but the public mind had already come to believe that the Jews were responsible for the abuses attributed to capitalism. And when an orgy of financial speculation following the payment of the French indemnity resulted in a disastrous crash, the latent anti-Jewish hatreds flamed up and antisemitism became an organized political and social agitation. The public remembered the

prominence of a certain Jewish capitalist, Bethel Strousberg, in the group of speculators, and forgot that the financial abuses were first denounced in the Reichstag by Edouard Lasker, a Jewish leader of the National Liberals.

In the meantime there had been developing the racial doctrine of antisemitism which soon replaced the outworn religious arguments as the rationale of anti-Jewish agitation. The doctrine developed when the rather innocent literary and philological speculations of Ernest Renan and Max Müller were taken up by strongly nationalistic German agitators and popularizers. In the course of his studies on Semitic languages the French historian had allowed himself to make a number of sweeping generalizations on Semitic race and Semitic traits. Similarly in the writings of Müller, the doctrine of a common Aryan tongue as a basis of all the Indo-European languages was upheld, the writer going so far as to posit a race which spoke the original language, the Aryans (*q.v.*). Although both Renan and Müller denied the significance which was attached to their doctrines, the mischief was done and the precedent was established of discussing Jews and Christians as an antithesis of Semites and Aryans. In the writings of the popular German ethnologist, Friedrich von Hellwald, we see the complete doctrine in action. In an article "Zur Charakteristik des jüdischen Volkes" (in *Das Ausland*, vol. xlv, 1872, p. 901-06 and 951-55) he writes: "In the case of the Jews we have to do with an entirely different ethnic group. . . . This people, scattered and settled in Aryan Europe, is purely Semitic. From an anthropological point of view, the Jew who lives in our midst stands quite as far apart from us as the Arab, and the emphatic contrast between the two, usually indicated by the opposites Christian and Jew, is for the most part exactly the same as the opposition which exists between Aryanism and Semitism. The European feels so to speak instinctively in the Jew who stands over against him the foreigner who has immigrated from Asia. . . . The so-called prejudice is a natural sentiment. Civilization will overcome the antipathy against the Israelite who merely professes another religion, but never against the racially different Jew. . . ." Von Hellwald then goes on to repeat the familiar charges of Jewish business cunning, which he explains as a racial trait and which he puts forward as the reason why the Jew gets the best of the honest Aryan. "We cannot do otherwise," he continues, "than to designate the Jews as the very canker

from which the lands of Eastern Europe suffer. No means (provided they are not violent, for everything for which personal courage is demanded is opposed in general to the Semitic and especially to the Jewish character) are too wicked for them to use in order to secure a material advantage."

This pseudo-scientific doctrine was eagerly seized upon by Marr, Glogau and Eugen Dühring, and exploited in a flood of pamphlets. It became a political issue through the interplay of certain forces in German domestic politics. The court preacher Adolf Stöcker had organized a Christian Socialist party with principles paralleling those of Catholic Socialism and with the purpose of appealing to working men on the basis of a moderate program of social reform. All evidence seems to show that the party was not organized originally as an anti-Jewish party. But when Bismarck broke with the National Liberals (a bourgeois democratic party with a number of Jewish leaders), who had supported him in his *Kulturkampf* against the Catholics, circumstances conspired to turn the Christian Socialist party into an antisemitic party. Bismarck spoke of a *Kulturkampf* against the Jews (1879) and immediately a vast storm of anti-Jewish agitation was unloosed. Stöcker put himself at the head of the movement and called for a crusade against the Jews (1880-81). There were riots, and a petition was signed by 300,000 Prussian citizens calling upon Bismarck to exclude Jews from all national schools and universities and from all public offices. In the elections of 1881 the Conservative party was captured by the Christian Socialists and won over to antisemitism.

The political movement soon burned out, the antisemitic parties gradually breaking up into their constituent elements. There was a revival in the period around 1890, when Hermann Ahlwardt headed the movement, and of course a much greater revival after the World War. What is significant, however, is that through all the interchange of parties from 1880 to the present there have always been one or more parties frankly professing antisemitic principles. After the war, as a result of the prominence of Jewish names in the Russian and German revolutions, the identification of Jews with subversive radicalism was more emphasized than their identification with capitalistic abuses. Frequently, however, the two were combined, as in the propaganda of Hitler's National Socialist party. In Austria, where basic conditions have been

similar to those in Germany, there has been a strong Christian Socialist party, with principles sometimes mildly and sometimes violently antisemitic.

The complexity and intensity of German antisemitism are shown by contrast with the situation in France. There antisemitism has had a more theatrical history but less enduring roots. In 1883 Renan congratulated France that the ethnological theories about Semites and Aryans had no practical application in that country. Antisemitism, however, flared up in France as a side issue to the conflict of clericalism and anticlericalism. The political history of France since 1870 had been largely dominated by the struggle to make the Third Republic a lay state with a lay educational system. In this struggle the French Jews were naturally identified with the democratic and advanced parties of secular reform while the conservative, Catholic and royalist factions fought to maintain as far as possible the old order of things. The Jewish issue was introduced by the agitation carried on by a group of journalists with Catholic and clerical sympathies, who identified the Jews both with the abuses of high finance and with the "unpatriotic" socialist and anarchist propaganda. This clerical use of the Jewish issue, first introduced by Drumont in his *La France juive* (2 vols., Paris 1886) and in his newspaper *La libre parole* (1892), gradually gained the attention of more authorized representatives of the clerical parties. Drumont himself was chosen honorary president of the congress of Christian democrats, a group of young priests, journalists and politicians interested in Social Catholicism, which assembled at Lyons in 1895. The author of a work on Social Catholicism, Paul Lapeyre, described the Jews as a "devouring canker" in France and demanded their expulsion and transportation to some fertile but distant country where they would have to "reform their habits or die of want." A direct appeal to religious prejudice was made when he called the modern Jews "the descendants of those who crucified Jesus" (Moon, P. T., *The Social Catholic Movement in France*, New York 1921, p. 207). In the Chamber of Deputies a clerical deputy, Viscount d'Hugues, made the sensational charge (1894) that the Jewish financier Rothschild had given money to anarchist agitators in order to disorganize and corrupt the labor movement.

This clerical flirtation with antisemitism was turned into a boomerang by the Dreyfus case.

This isolated incident, willed by no organized party, committed the conservative parties to an official policy of antisemitism while it made pro-Dreyfusism the slogan which united the bourgeois anticlerical parties and the socialists. The victory of the Dreyfusards destroyed antisemitism as a political issue in France and damaged the clerical parties. Antisemitism was left as a social prejudice, exploited occasionally by the royalist Action Française group, and by the obscure periodical *La vieille France*. This agitation was revived to a certain extent after the publication of the Protocols of the Elders of Zion but otherwise it has been quiescent.

Turning to Russia and eastern Europe one beholds a type of antisemitism quite different from those described thus far. Both because of the concentration of the Jewish population and because of the economic and social conditions of these countries, the Jewish problem is mediaeval in character. In the Russia of the old regime the Jews were considered a separate economic and religious class and their status was regulated accordingly. For the most part they were forbidden to reside outside of the territories of the old kingdom of Poland, which thus constituted their Pale of Settlement. The political reaction which followed the assassination of Alexander II (1881) further increased their disabilities. Under the celebrated May Laws (1882) a pale was created within a pale—that is to say, even within the Pale of Settlement the Jews were forbidden to reside outside of the towns—with the object of preventing the Jews from owning land. In addition a *numerus clausus* or fixed quota varying from 3 to 10 per cent was enacted to govern the admission of Jews to the universities and schools of higher education. In the meantime there had taken place a series of bloody pogroms, in large part stimulated by the reactionary government in power as a distraction to the political discontent of the masses. These were the forerunners of greater pogroms in 1903 and 1906 when the Black Hundreds were organized by the government as a deliberate method of combating the revolutionary movement.

Aside from physical excess Russian antisemitism under the old regime is chiefly significant for its cold blooded political exploitation of anti-Jewish hatred. This use of anti-Jewish feeling was of course not unknown in the Middle Ages, when more than one king incited the populace against the Jews in order to avoid paying his debts or in order to plunder them for

their money. But it was reserved for the Russians to organize this sort of propaganda as a fine art. Their most notable achievement—and one that had sensational international consequences—was the perpetration of the forgery of the Protocols of the Elders of Zion. This forgery was finally and conclusively exposed by the *London Times* (*The Truth about the Protocols*, London 1921) but not until the story of an extensive conspiracy to bring the world under Jewish dominion had been circulated in all countries and had played an important role in stimulating antisemitic agitation in countries hitherto relatively free from public antisemitism, such as England and the United States.

The protocols first appeared in Russia in 1905, when they were published by Sergey Nilus, who claimed that they were obtained by a woman who stole them from "one of the most influential and most highly initiated leaders of Freemasonry . . . at the close of the secret meeting of the 'initiated' in France, the nest of Jewish conspiracy." In the edition of 1917, which was circulated after the Bolshevik revolution by Russian monarchists in England and the United States, Sergey Nilus added new details. He claimed that the manuscript had been given to him by the Russian official Sukhotin, and that the protocols were notes of a plan submitted to the "Council of Elders" by Theodor Herzl at the First Zionist Congress at Basel in 1897. Like the blood ritual accusation the protocols were seen to be obviously fraudulent by every one acquainted with Jewish life. The motivation of the fraud was evident on its face, and its use in both Russian revolutions was sufficient to make one suspect its origin. Nevertheless the protocols were widely credited and were actively circulated by reactionary groups who either "willed to believe" or willed to make others believe in their truth. By fortunate circumstance the *London Times* correspondent at Constantinople was able to put his finger on the actual origin of the protocols and to demonstrate that not only were they a hoax and forgery in the ordinary sense but in addition a literary plagiarism. The greater part of the text of the so-called protocols was shown to have been taken from a political tract published in 1865 and 1868 by a French republican and aimed at Napoleon III (who had the author imprisoned for his offense). All that the anonymous forger—evidently a Russian secret police official—had done was to change the text here and there and add a Jewish and Marxian flavor.

The episode of the protocols throws into relief the public situation of the Jews after the World War and the Russian Revolution. It also ties together in a curious way the tangled affairs of eastern Europe with the problems of America. The circulation of the protocols in the United States coincided with a wave of feeling against the recent immigrant stocks in which for the first time antisemitism came to the surface as a public phenomenon. The World War had produced, or at least crystallized, a reaction against the "melting pot" policy of welcoming all races, maxims and creeds to the land of freedom, and this reaction was directed against the Jews along with the rest of the so-called "newer immigrants." This reaction was increased by the impact of the Russian Revolution, which was at first welcomed even by the conservative element as a victory of democracy over czarist absolutism but which was soon felt to be a menace to American institutions. The distrust of the foreign born was magnified by a fear of radicalism, and in the latter respect the Jews found themselves singled out even more than other foreign stocks because of the prominence of Jewish names among the Russian Bolsheviks.

This is not to say that American antisemitism is altogether the product of post-war conditions. Even before the war antisemitism existed as a basic social-psychological sentiment. This sentiment found its expression in the exclusion of Jews from fashionable hotels and summer resorts and in discrimination against Jews as employees in the business world. Along with these manifestations may also be mentioned a certain discrimination against Jews as students and faculty members in the colleges and universities. But it was not until the period of 1917-25 that people began to talk openly of antisemitism. It was in this period that the agitation against the "international Jew" was carried on by the *Dearborn Independent*, owned by Henry Ford, who later publicly disavowed the attacks on the Jews. It was also in this period that the Ku Klux Klan was revived to function against Negroes, Catholics and Jews. Finally the same period saw the enactment of the new immigration laws which had as one of their purposes the limitation of Jewish immigration from eastern Europe.

For a few years it looked as if America were soon to find itself in a class with Germany and east European countries in respect to its Jewish problem. But these surface indications were belied by the underlying socio-economic conditions. While antisemitism primarily operates

as a psychological sentiment, it must not be forgotten that this psychological sentiment is conditioned in various ways by the physical structure of social life. Despite the discrimination against Jews in the business world, economic opportunities remained wide open, and in the long run it is this freedom of economic opportunity—particularly remarkable in a growing country like the United States—which counts for more than even the most deep rooted psychological sentiment.

People who approach the Jewish problem without a sense of history and without a sense of the whole are prone to erect a metaphysics of race and nationalism which eventually becomes an obstructive factor in the situation. The real but relative state of facts which is behind the system of Jewish-Gentile group sentiments is transformed by such persons into transcendental entities which forever preclude change and development. Jews, they say, are a different race, a different national group, and cannot be assimilated. Now it is one thing to use the categories race, nation and group as concepts describing distinctions in a given social or biological context, but it is quite another thing to extrapolate these categories into the timeless world of logical necessity and to assume thereby that the distinctions of the present will hold and ought to hold in the future.

As a matter of fact the very sociological situation which reveals the distinctness and rigidity of such categories also reveals their interaction and interpenetration. There is no biologically pure race, there is no 100 percent nation to be found anywhere in the world. There is always a crisscrossing and conflict of categories. Here it is religion which cuts across nationalism, there it is biological and cultural kinship; somewhere else it is economic and class loyalty. And finally there is even the spirit of internationalism, which for many men commands a certain loyalty over and above some of the other loyalties.

The conflict of group lines represented by antisemitism is thus in no wise unique. Basically the same social problem is repeated over and over again in other group clashes—some of which are nearer and some of which are even farther away from permanent solution than the Jewish problem. Geographic nationalism and its quota of hatreds seem to us more normal than antisemitism only because the phenomenon is more usual. Color lines too seem to us more rational only because the imagination has some-

thing visible and palpable to point to as the cause. In the case of antisemitism the cause of the group distinctions is buried in historical tradition and the ever changing combination of economic and social forces, but the phenomenon is otherwise the same. Perhaps antisemitism will lose its mysteriousness when it is realized that there is nothing specially abnormal or unnatural in the existence of a Jewish group among the various groups which constitute a society.

ANTITRUST LAWS. See TRUSTS.

ANTON, KARL GOTTLOB VON (1751-1818), German writer on legal and economic subjects. As a young man he engaged in the study of ancient German law, translated Tacitus' *Germania* (Leipsic 1781) and published *Über die Rechte der Herrschaften auf ihre Unterthanen und deren Besitzungen* (Leipsic 1791). He was an ardent German patriot (see his *Geschichte der deutschen Nation*, Leipsic 1793), and manifested a special interest in the Slavs of his home province and in their national regeneration (see the exchange of letters between Anton and Dobrowsky, reprinted in *Oberlausitzische Gesellschaft der Wissenschaften, Neues Lausitzisches Magazin*, in 1841 and 1843). As a result of this interest Anton published *Erste Linien eines Versuches über der alten Slatonen Ursprung, Sitten, Gebräuche* (2 vols., Leipsic 1783-89). His chief work is the *Geschichte der*

teutschen Landwirtschaft von den ältesten Zeiten bis zu Ende des xv. Jahrhunderts (3 vols., Görlitz 1799-1802), a work of cultural history which has furnished valuable material for later students. In it he attempted to present the history of agriculture on the basis of contemporary sources, and it is important to note that he assumed, even at the time of Tacitus, the existence not only of individual property in arable land but also of manorial estates. In the course of preparation of this work he had occasion for philological research also, and this led to his publication of *Über Sprache in Rücksicht auf die Geschichte der Menschheit* (Görlitz 1799).

ALFONS DOPSCH

ANTONINO, SAINT (1389-1459), Florentine churchman and writer on economics and morals. Antonino became prior of Cosimo de' Medici's San Marco in 1439 and archbishop of Florence in 1446. He was canonized in 1522. As archbishop he established the *Provveditori dei Poveri Vergognosi* (now known as the *Buonomi di S. Martino*), a society of social workers who provided the needy with medical attention, gave dowries to marriageable girls who would not otherwise have been provided for, paid apprenticeship fees, redeemed pawn tickets and supplied money, food, bedding and clothes to the poor. In laying down the rules for the government of this society Antonino forbade the funding of moneys received, as well as the assumption of the administration by any civil or ecclesiastical authority. He also reorganized the *Spedale degli Innocenti* for illegitimate children, reestablished the Bigallo orphanage and advocated the establishment of public schools and the construction of public roads and fine buildings.

More important than Antonino's social practices are his social theories. His *Summa moralis* (4 vols., Verona 1740) is a mine of information on matters economic as well as moral. He treats of production, distribution and consumption and views each of these from the general standpoint that everything man does should have a purpose which directs and limits it. All ills of social life come from a neglect of the important principle that man should earn to live and not live to earn. Trade, although marked by many malpractices, is in itself a unifying principle in the *corpus mysticum* of Christendom, since it allows each national unit to contribute its particular wealth to the benefit of all. International

commerce, therefore, should be based on the moral principle of cooperation and not on the false principle of competition. In analyzing price Antonino distinguished between value based on inherent, objective properties of a commodity and value resulting from the rarity, utility and pleasurable nature of the commodity to the individual using it. It is this latter type of value which is the determining factor of price. In the regulation of prices account must be taken of demand and supply, of the value of the commodity to the purchasers as well as of its cost of production and of social as well as of individual considerations.

Antonino was a realist who passed moral judgments on the basis of close observation of actual conditions. Living in a period of great commercial development he admitted the productivity of capital while denying the productivity of coin and thus justified some form of interest. He analyzed and evaluated the activities of the *montes* and the claim of their shareholders to profits. Because of the distress in Florence he favored the fixation of prices and wages by a government appointed committee of prudent men, which should not include ecclesiastics. While he believed that the inequalities of property are inevitable he insisted that decent living conditions should be provided for all. In return the state should compel men to work, if they would not do so of their own accord.

BEDE JARRETT

ANTONOVICH, VLADIMIR BONIFATIEVICH (1834-1908), Russian historian, ethnographer and archaeologist. A scion of Polish gentry of the province of Kiev, he renounced as a youth his Polish nationality and joined the Ukrainian nationalist movement. In his opinion the intelligentsia could better serve the masses if it accepted their national tradition as its own (see his "credo" in the St. Petersburg magazine *Osnova*, 1862). After graduating from the faculty of medicine (1855) and from the faculty of history and philology (1860) of Kiev University, he taught history for three years in the secondary schools and in 1863 joined the staff of the Governmental Temporary Commission for the Investigation of Ancient Records. He soon became chief editor of its publications and retained this post until 1880. In 1878 he was appointed

professor of Russian history at the University of Kiev. His publications in *Arkhiiv Yugo Zapadnoy Rossii* (Annals of Southwestern Russia), an organ of the commission, include reprints of a large number of historical records and a long series of articles relating largely to the history of the struggles between the native population of the southern and western provinces and Poland from the fifteenth to the eighteenth century. The more important of these are: "The Cossacks," "The Uniat Church," "The Last Days of the Cossacks on the Right Shore of the Dnieper" and "History of the Grand Duchy of Lithuania." A follower of Kostomarov in his interpretation of Ukrainian history, he belonged to the populist school. By encouraging research in the history of separate Russian territories he is responsible for the creation of an entire group of local historians. As a result of his interest in folklore he published "Records on Witchcraft," based on archive material, and, with M. D. Dragomanov, a collection of historic songs of little Russians (*Istoricheskiya pesni malorusskavo naroda*, 2 vols., Kiev 1874-75). The later part of his life was devoted largely to archaeological work. He directed many excavations of graves and town sites in Ukraine and was active in regional and international archaeological congresses. His activity as a nationalist was primarily cultural: he delivered privately historical lectures in Ukrainian, he issued a formal protest against the prohibition of printing in the Ukrainian tongue (1876) and was one of the founders and important collaborators of *Kievskaya Starina* (Kiev Antiquities), a magazine for the study of Ukrainian history. He is also given credit for the reconciliation effected about 1890 between Ukrainian and Polish leaders of Galicia; it made possible the establishment of several Ukrainian chairs at Galician universities.

V. MIKOTIN

ANUCHIN, DMITRY NIKOLAYEVICH (1843-1923), Russian anthropologist and archaeologist. He was graduated from the University of Moscow in 1867. At first he specialized in zoology, but he soon became interested in anthropology, prehistoric archaeology and geology. After several years' study in the uni-

versities of England, France, Germany and Italy he was appointed in 1880 professor of anthropology, when the chair of anthropology was founded in the University of Moscow. He lectured also on ethnology and geography in the university and on archaeology in the Moscow Archaeological Institute.

During his long career as a teacher Anuchin trained several generations of well known specialists in various lines of anthropology and related sciences as teachers, writers and field workers. Many of his works are magnificent contributions to the history, palaeoethnology and archaeology of Russia. For about half a century he was president of the Moscow (former Imperial) Society of Friends of Natural Sciences, Anthropology and Ethnography, and chairman of its anthropological and geographical divisions.

Anuchin was not only a prominent scientist but was also actively interested in the political life of his country. For many years he was connected with the outstanding liberal daily paper in Russia, the *Russkiya Vedomosti* (Russian Gazette), as one of its publishers, editors and contributors.

WALDEMAR JOCHELSON

Important works: *Luk i streli* (Bow and arrows) (Moscow 1887); *K istorii oznakomleniya s Sibir'u do Yermaka* (Contributions to the history of relations with Siberia before Yermak) (Moscow 1890), German tr. by H. Michow in *Anthropologische Gesellschaft in Wien, Mitteilungen*, vol. xl (1910) 1-21; *Sani, ladiya i koni, prinadlezhnosti pokhoronnovo obriada* (Sledges, boats and horses as accessories at burial ceremonies) (Moscow 1890), summarized by J. O. Wardrop (London 1892).

ANZANO, TOMÁS DE (died in 1795), Aragonese public official and writer on economic subjects. Using terms he would not have recognized, we may classify Anzano as a pragmatist, relativist, nationalist and mercantilist. Evincing little ability or inclination to reason abstractly, he treated value vaguely, omitted distribution and had no conception of a general price level or of the connection between money and prices. He condemned luxury, forestalling, indiscriminate almsgiving, laissez faire, the corvée, métayage and depreciation of agriculture, and advocated government intervention in economic matters, the use of oxen in plowing, the extension of irrigation, diversified agriculture and the organization of a company to aid agriculture and small manufactures. Some of Anzano's schemes were visionary but others proved practicable.

APORTI, FERRANTE (c. 1792-1858), Italian educator. After studying at Cremona he was ordained a priest in 1815 and went to Vienna to complete his theological education. There he made the acquaintance of G. Wertheimer, who popularized Wilderspin, and attended the lectures of V. E. Milde, a follower of Pestalozzi. In 1821 he was charged with the direction of the larger elementary schools of Cremona and in that capacity discovered his true vocation—infant education. About 1829 he founded the first real pre-school institution or kindergarten in Italy, which he called an "infant school." This was followed in 1831 by a free infant school for children from three to six years of age, and in fifteen years' time the number of "infant asylums" established by his efforts had grown to one hundred and seventy-eight.

The value of his infant asylums consisted essentially in the idea of play as a formative occupation for the child and in the organization of material for primary instruction in such a form that it could be mastered in informal conversation with the mother. He knew the works of the Englishman Wilderspin, the man who put Owen's educational theories into practise, but his institutions were fundamentally Italian. In Piedmont he had as coworkers Boncompagni and Cavour; in Tuscany, Raffaello Lambruschini. The popular reform movement of the period in Italy included in its program the establishment of infant asylums modeled after Aporti's schools.

In the Revolution of 1848 Aporti ranged himself against Austrian domination. He was banished in 1849 and took refuge in Piedmont, where he continued his educational work.

APOSTASY AND HERESY. Apostasy in classical Greek was a term signifying a defection or revolt from a military commander. Thus from the beginning it was used in an opprobrious sense. It has been most commonly used to describe the complete renunciation of the Christian faith, although it may also be applied to other religions. In recent times it has been employed abusively as a term of reproach for sudden changes in political opinions. However applied, apostasy has consistently signified a desertion of the standard of the group at some point considered vital to the well-being, if not the actual existence, of the group. Apostasy belongs in the class of serious violations of the mores rather than of variations in the folkways of society.

The idea of apostasy emerges in the literature of the Jews in the period of the Maccabees. The persecution by Syria and the more subtle onslaught by Hellenism were the twin perils of Israel at that time. From the situation of the Jews, apostasy was doubly serious because it involved a desertion of both the religious and the national cause at a time when Israel was in a precarious situation in both respects. The vehemence of the rabbinical language on the subject is therefore easy to understand. The *Jewish Encyclopedia* quotes rabbinical statements of the time which declare that "no sacrifice is accepted from the apostate," and add: "nor have they any respite from eternal doom in Gehenna."

In the early years of the Christian church converts were led by persecution or the fear of violence into denying the faith. Their defection was thus due to the unworthy motive of self-protection, and apostasy struck at the very life of the church. The apostate was the renegade who deserted his brethren in their time of need, signifying his return to paganism by some outward act such as offering incense to a heathen deity.

Heresy, which in latter centuries was identified with apostasy for practical purposes, had a much milder origin, the Greek equivalent signifying free choice. Used for a time to apply

to philosophical schools, it later referred to religious parties such as the Sadducees, Pharisees and Essenes. Christianity was termed by its opponents a heresy. The term formerly had much the same meaning as schism and was applied to theological errors. As organization of the church proceeded, doctrine became more important and heresy was restricted to any departure from the recognized creed. In the ante-Nicene period the Christian church was in serious danger of pollution or destruction by the pagan and Jewish elements which threatened to become blended with the faith. At this time the punishment of heresy was by reproof and excommunication. In the post-Nicene period heresies became less significant differences in interpretation of Christian truth. As long as the church was persecuted by the pagan empire it advocated freedom of conscience, but almost immediately after Christianity was adopted as the religion of the Roman Empire the persecution of men for religious opinions was undertaken by the church. By canon law heresy became not only an error but a crime to be detected and punished. Just as apostasy carried the common conception of unworthy motivation, so heresy came to be associated with wilful and persistent opposition to truth.

Apostasy was the overt act of deserting to the enemy; heresy was the insidious danger which threatened to split the group into warring factions. Apostasy depends upon a conflict of religions; heresy may develop at the center of the religious order. The Emperor Julian deserted Christianity for paganism and became known as "the Apostate"; Martin Luther challenged certain practises of the Catholic church, and the Reformation itself was a heresy from the standpoint of the Roman Catholic. The heretic may deny only one of the doctrines of revealed religion, while the apostate denies the religion itself. As church and state became closely allied, the dangers of severe punishment for minor differences brought heresy and apostasy closer together, since the heretic might find himself driven into the more complete denial of all the practises and beliefs of the group threatening him.

Apostasy was at first included in the class of sins for which the church imposed perpetual penance and excommunication without hope of pardon on this earth. In 251, however, the right of the church was admitted to remit the sin of apostasy. When the Roman Empire became Christian, apostates were punished

also by deprivation of all civil rights. They could not give evidence in a court of law and could neither bequeath nor inherit property, while to induce anyone to apostatize was an offense punishable with death. In the Middle Ages civil and canon law classed apostates with heretics, and the same punishments were applied.

As the church grew in power and in the refinement of its canon law, ways multiplied in which Christians could become apostates, and the church became increasingly skilled and zealous in detecting the offense. An elaborate system of tribunals was gradually developed for passing judgment and awarding punishment. The major instrument developed by the Catholic church for dealing with apostates or heretics was the Inquisition. Various plans and practises were used, most of them far milder than the famous Inquisition in Spain. The papal states maintained councils which rarely if ever inflicted the death penalty. In the northern countries houses of bishops were assigned the work of examination. In the thirteenth century, however, the technique and theory of the Inquisition had made such progress that Gregory IV entrusted the Dominicans with the task of running down heretics and handing them over to the civil authorities for execution. The Spanish Inquisition, so fierce that it was tolerated rather than sanctioned by Rome, was directed principally against backsliders among the Jews and Moors who had been ostensibly converted to the Christian faith out of fear for their lives and property. In general the force of the Inquisition and other tribunals for judging and punishing apostates and heretics was spent when the various nations took over all rights of punishment with the exception of such spiritual sentences as excommunication. With the full development of civil judiciary systems the excitement over apostasy rapidly waned.

Not only did apostasy and heresy cease to be clear cut conceptions among non-Catholics following the Reformation, but the churches of all sects found themselves facing larger problems than the disciplining of erring individuals. It is true that nonconformists in England and on the continent and, later on, in New England found themselves victims of sporadic persecutions and Protestant inquisitions, but the back of the movement to compel regularity in religion was broken by the multiplicity of orthodoxies and by the successive revolutions caused by the discoveries, the inventions, and their offspring,

the economic revolution. The period was one of mass apostasies, with no church great enough to stem the movement. The first of these mass apostasies was from the state church, and took place in defiance of the Protestant as well as the Catholic church. Following close on this separation of church and state came the apostasy of the economic world from allegiance to church authority. None protested more loudly than the Lutheran, Calvinist and English clergy against the usurers, merchants and employers who defied the law of God, yet the age passed rapidly into an almost complete separation of the economic from the church world. The loss of the church's political and economic provinces would have seemed to her disastrous enough. But society itself, in its vaguer definition, embarked upon an apostasy from ecclesiastical authority which, with temporary checks by Calvinist or Puritan societies, has progressed to the point where at present only vestigial traces of the old direct church laws remain.

The Roman Catholic church still imposes penalties for heresy, particularly in the case of desertion of a religious order after vows have been taken, but all religious groups have become less eager to hunt out the milder heresies. Desertion of the faith no longer appears as a vital blow against the survival of the group. The development of a new religion, however, with a tight religious organization struggling for existence against a hostile world, would put a new importance upon the apostate, as exemplified in the last century by the terroristic practises of the Mormons. At present the apostate in Protestant circles is subjected to slight discrimination if any, dependent upon the customs of his locality and particular group.

APPANAGE. This term is used to designate the territory in vassal hereditary possession held by a member of a ruling dynasty. The appanage

system was of some importance in France and of even greater importance in Russia. With the establishment of primogeniture in the succession to the throne of France there arose the custom of endowing the younger sons of the king with feudal estates, or appanages, and from the time of the testament of Louis VIII in 1225 the system was practised on a large scale. The creation of these appanages tended to diminish the domain of the Capetian kings and to favor the formation of a new feudal aristocracy which stood in the way of royal centralization and which became particularly troublesome during the reign of Louis XI (1461-83). On the other hand the distribution of members of the royal family throughout France resulted in the introduction of language, customs and administration similar to those of central France and thus facilitated the ultimate acceptance of Capetian domination. By successive measures the transfer of appanages by inheritance was restricted and the possibilities for their reversion to the crown so expedited that they became relatively unimportant after the sixteenth century.

In Russian history the appanage system flourished from the end of the twelfth to the end of the fifteenth century, the period of transition from the supremacy of Kiev to the unification of the country under the Moscow princes. Its characteristic feature was extreme division of territory into large and small princely possessions enjoying sovereign rights and claiming independence.

In the Kiev period the dynasty had kept the whole territory in collective undivided possession, every member of it holding a respective part of the territory according to priority of birth. There was thus a correspondence between the genealogical hierarchy and the hierarchy of holdings which were ranked in the order of their comparative revenue yield. The oldest member of the family had the title of grand prince and the residence of Kiev, which after his death passed to his next brother (not son); the other brothers and after them their sons each moved one step nearer to Kiev. This order of succession, founded in 1054 by the Russian Charlemagne, Yaroslav, soon gave way to the system of succession from father to son. Even as early as the conference of princes at Liubech (1097) direct succession was sanctioned as a general principle. However, it took root not in the southwest but in the newly settled regions of northeastern Russia dominated by Suzdal and Vladimir.

In those provinces there soon appeared several local dynasties, each of them establishing within its own territory hereditary appanages which in turn were divided into still smaller ones and which gradually became indistinguishable from mere *seigneuries* (*boyarshchina*). The holder of an appanage exercised the powers of a sovereign in matters of taxation and administration of justice and in addition was free to render military service to whomsoever he pleased. If he served the prince of his own lineage, the older relationship of elder brother or father was preserved. If, however, he chose to transfer his military strength to some outside prince, his property still remained under the sovereignty of the head of his own line.

As time went on, the more powerful among the possessors of appanages acquired complete independence from the principal grand prince and founded their own grand principedoms (e.g. Tver, Riazan). By mutual agreement they forbade the free transfer of allegiance by their vassals. When the grand prince of Moscow annexed other grand principedoms and small principedoms he imposed a similar restriction. With the completion of this process of annexation the only remaining choice was to transfer allegiance to the enemies of the "whole Russia," such as the Polish-Lithuanian state. Finally John IV (1547-84) confiscated the appanages of remaining great and small (*kniashata*) princes, exchanged them with other properties in the remote parts of the unified Russia and deprived the princes of all rights of their sovereignty. The Middle Ages in Russia, so similar to the period of feudalism in western Europe, thus came to an end.

PAUL MILIUKOV

APPEALS. Appeal in modern law signifies the judicial process whereby error in an inferior tribunal is corrected in a superior one. In its earlier sense, however, "appeal" meant an accusation. The derivation from *appellare* shows

that it was first understood as the individual's outcry against injustice. The allowance of appeals is very uncommon in early stages of legal development. Where justice has a popular basis (as in the clan) an appeal would be anomalous. When administrative, legislative and judicial functions begin to be separated, the process is equally unfavorable to appeals. The extreme formalism and rigidity of early legal procedure put the emphasis merely upon the observance of the proper rules. Since in early stages of legal evolution the judge is essentially an arbitrator appointed by the parties to decide a single controversy, it is considered that they have specifically agreed to abide by his decision. When he has rendered it, moreover, his authority is conceived to have been extinguished so completely as to make recourse impossible. When a multiplicity of courts and magistrates does come into existence, they are not related in a hierarchy but represent independent jurisdictions arising from the differentiation of various administrative functions. A consciousness of a difference between "criminal" and "civil" appeals also comes later, although where democratic sentiments have prevailed some form of appeal has been invented in the interest of the life of the individual. Above all, appeals imply a sophistication of outlook with respect to the judicial process and a conception of authority alien to early communities, in which judgment was considered such a solemn act that it must stand even if wrong. At first appeals consisted not in seeking the judgment of a higher court but were rather a personal remedy against the individuals who had abused their office; thus they charged the judge personally with wilfully giving a false judgment, or the witnesses to the facts with perjury.

These tendencies may be observed in the development of Greek and Roman law. In Athens as long as the judicial business was divided among the archons each was supreme in his own field. With the advent of democracy, in which the people claimed to exercise all the functions of government, it was seen to be impossible to allow magistrates to render final judgment. Thus one of the reforms of Solon was to allow a right of appeal from magisterial decisions to the people assembled in the Heliaea, the judicial assembly. But to appeal beyond the assembly would imply a negation of popular sovereignty. In fact, Clisthenes finally made the heliastic courts courts of first resort rather than courts of appeal. While, strictly speaking,

no appeal could be taken from the judgment of a heliastic court, a new trial could be had by the successful prosecution of a witness for perjury which included illegal as well as false evidence. It was not till Pisistratus set up itinerant circuit judges for the Attic townships that some forms of appeal developed. Similarly in Roman law the right of *appellatio* was not recognized until after the establishment of a magisterial hierarchy under the empire. Under the formular procedure great difficulty was experienced in allowing appeals. As far as the magistrate was concerned his *imperium* interposed. The arbitral character of the *iudex*, for the very reason that he was without *imperium*, had the same effect. The way out was found in the contractual nature of the formula. While there could be no mistake in the judge's sentence, actions of restitution might be based on mistakes in the formula. As far as "criminal" cases were concerned in which death or corporal punishment might be inflicted on a Roman citizen, there was developed the right of *provocatio*, which permitted the condemned to appeal from the magistrate's sentence to the people assembled as the *Comitia Centuriata*.

The development of appeals in early English law is somewhat similar to this course of evolution. Appeal in its modern meaning is probably not older than the end of the thirteenth century, and is derived from ecclesiastical sources. However, for several centuries the common usage of appeal denoted an accusation of felony by aggrieved private individuals as in "appeals of murder," which remained indeed the common way of prosecuting this crime until the end of the fifteenth century and was not formally abolished until 1819. Appeal as a method of correcting error was at first probably inspired as much by a desire to establish the royal prerogative in the period of centralization which witnessed the decay of feudalism as by a desire to prevent injustice to individual suitors. Appeal was implicit in the hierarchy of the feudal system and was bound to be elaborately organized as soon as local and private jurisdictions gave way before the royal claims. There had developed before the end of the fifteenth century a system of royal courts—the Common Pleas, the Kings' Bench and Exchequer on the law side, and Chancery on the equity side. Ancient local courts continued to operate, as did certain ecclesiastical tribunals, although they were of decreasing importance. The royal encouragement of seeking relief in

Chancery against unjust although strictly legal judgments of the common law courts was essentially the encouragement of a way of appeal which, without formally invalidating judgments that had been obtained in the common law courts, rendered them unenforceable.

It was inevitable that conflicts of jurisdiction should arise and that dissatisfied litigants should seek a reexamination of their cases. In the common law courts writs were invented to remove litigation from the local to the royal courts and to prevent undue meddling in temporal matters by ecclesiastical courts. Means for reviewing unsatisfactory decisions in the royal courts were devised. The alleged error might lie in the verdict of the jury. If so, the original remedy was by attain of the jury for its misfeasance. The defeated litigant secured another jury of greater number and higher dignity, to which the original question was submitted. If its finding was contrary to the first verdict, that verdict was invalidated and the jurors who had rendered it were heavily punished. The severity of the penalty inflicted upon the attainted jurors operated to prevent the attain from developing into a satisfactory device for correcting mistaken verdicts. Although it was not abolished until 1825, it was of little use after the middle of the seventeenth century. The justices from the beginning rejected or set aside verdicts from jurors who had been guilty of misconduct. But they had much greater difficulty in interfering with verdicts as unfounded in fact, since until the early eighteenth century jurors were entitled to rely upon their own private knowledge. It would be a rare case in which the judges could be sure that such facts as indisputably appeared in court might not be counterbalanced by something known privately to the jurors. Yet the failure of the attain and the competition of equity compelled the common law judges to extend their control over the jury. Consequently from the latter part of the seventeenth century erroneous verdicts have been nullified by granting new trials.

Similarly, unsatisfactory decisions of a local court might be reexamined in a royal court under a writ of false judgment. This writ originally predicated fault on the part of the court, as the attain did on the part of the jury. By a similar process the judgments of itinerant justices and justices of assize were brought under review. The King's Bench assumed the power to rectify errors of the Common Pleas. Any

error of record in form or substance caused reversal, but rulings respecting evidence and instructions to the jury were not of record until legislation of 1285 and later permitted them to be preserved for review. Subsequent enactments forbade reversal for unsubstantial errors. Until the erection in 1858 of a Separate Court of Exchequer Chamber with jurisdiction in error over the King's Bench, the only tribunal superior to the King's Bench was Parliament. In 1357-58 a Court of Exchequer Chamber had been created to correct the errors of the Exchequer. In 1830 the two courts of Exchequer Chamber became a single court of appeal from the common law courts, and the King's Bench was deprived of appellate jurisdiction. In Chancery, where trial was without jury and all proceedings from an early date were required to be in writing, there was elaborate reexamination within the court. When the Master of the Rolls rendered a decree, it might be reopened before him by a petition for rehearing; it might then be heard and again reheard by the Chancellor, and at each hearing new evidence might be received. Before 1851, when a Court of Chancery Appeals was established, there was no appellate review short of the House of Lords. The House of Lords exercised a jurisdiction in error over the courts of common law, over the law side of Chancery and, after the middle of the seventeenth century, over the equity side. In equity appeals it took no new evidence. In 1873-75 the courts were consolidated by the Judicature Act; law and equity were fused and writs of error were abolished. A Court of Appeal was erected which, following the Chancery practise, entertains appeals by way of rehearing. Final resort is to the House of Lords and in a few categories to the Privy Council.

Thus was evolved the system of review in civil cases; in criminal cases progress was slower. An acquittal was final. There was no attain. There was no new trial after conviction of felony, although it might follow erroneous conviction of a misdemeanor. For errors of law appearing strictly of record, a writ of error was obtainable. A trial judge might also in case of conviction exercise his discretion to reserve a doubtful point of law for consideration by his brethren and, after 1848, by the judges of the Court of Crown Cases Reserved. If it were resolved in favor of the prisoner, a pardon followed. It was not until 1907 that the Criminal Appeal Act provided for a rehearing by an appellate court. The Court of Criminal Appeals

reviews the entire case and may receive new evidence. A final appeal to the House of Lords may be made only when the attorney general certifies that the case "involves a point of law of exceptional public importance and that it is desirable in the public interest that a further appeal should be brought." Since 1875, therefore, in civil cases and since 1907 in criminal cases, England has enjoyed a system of appellate review wherein the scope of the reexamination is not substantially hampered by technical restrictions.

It is apparent that until the reforms of the Judicature Act the appellate jurisdiction of the various English courts was often largely the result of historical accident. The right to review exercised by various courts was based rather on functional than hierarchical considerations. As we approach modern times, however, we find systems of courts more consciously created in a relation of lower and higher degree. This logical hierarchy is based, it is true, on subject matter and the magnitude of controversies, but the exigencies of appeal are also a very determining influence. When, after the separation from England, a hierarchy of courts was created in the United States, the existing English procedural devices were naturally adopted or continued. The appellate courts reviewed the judgments of inferior common law courts by writ of error and the decrees of equity courts by appeal. The appellate jurisdiction of the hierarchy of courts assumed great importance in view of the federal structure of the government.

At present the appellate judicial power of the United States government is vested in the several Circuit Courts of Appeal and in the Supreme Court. For each of the nine judicial circuits and for the District of Columbia there is a Court of Appeals, which has appellate jurisdiction over the respective district courts, save where a direct review by the Supreme Court is authorized, and over certain quasi-judicial boards and commissions. It may, to secure aid for reaching a correct determination, certify to the Supreme Court specific questions of law. It may be required by that court to transmit any pending case for decision or any decided case for review. If it holds any state statute invalid as repugnant to the constitution, treaties or laws of the United States, the defeated litigant may, as of right, resort to the Supreme Court. Besides exercising this supervisory power over these courts of appeal, the

Supreme Court directly reviews, by appeal, the decrees of the district courts in suits to prevent the enforcement of state statutes or orders of certain boards and commissions, and in suits by the United States to enforce the antitrust and interstate commerce laws, and decisions of district courts adverse to the United States in certain criminal cases. If a state court of last resort decides against the validity of a treaty or statute of the United States, or sustains the validity of a state statute against a claim that it is repugnant to the constitution, treaties or laws of the United States, an appeal lies to the United States Supreme Court. In all other cases where a federal question is decided by such a court, the Supreme Court has a discretionary power of review. It exercises appellate jurisdiction also over the Court of Claims, the Court of Customs' Appeals and the Supreme Court of the Philippine Islands. The appellate courts in reexamining decrees in equity cases rehear the case on the record as made in the court of first instance. In reviewing judgments or appealable orders in law cases, they determine questions of law only. When considering a decision of a state court of last resort the Supreme Court confines itself to a determination of the federal question of law presented by the record.

The pertinent state enactments are so variant that it would require volumes to expound them. Generally speaking, three methods of appellate treatment are prescribed. First, the appellate tribunal may have to retry the entire controversy. In such event it handles the case like a court of first instance. This method is often required in appeals from the judgments of justices of the peace to courts of general original jurisdiction. It sometimes obtains also in the reexamination of decisions of probate or surrogate courts. It is rarely, if ever, used in courts of last resort. Second, it may be directed to rehear the cause on the record made in the lower court, either alone or supplemented by new evidence. Here it makes its decision as it would have done had the questions of fact and law been originally presented to it. This is substantially the original English Chancery procedure and is frequently used in the review of decisions in equity. Very rarely, however, is any provision made for taking any substantial testimony in the appellate tribunal. Third, it may be authorized to review every ruling of law made by the trial court, including its decision on the question whether the verdict or

finding has any evidence to support it. If reasonable men might draw different conclusions from the testimony, the verdict or finding will stand, even though it be against the preponderance of the evidence. The trial judge may usually grant a new trial because errors of law occurred during the trial or because the verdict is contrary to the great weight of the evidence. In the former case his action is in many states reviewable; in the latter, if reviewable at all, it is reversible only for abuse of discretion. In a few places express authority to reverse is given where on the whole record manifest injustice appears to have been done. This third method is generally provided for the review of cases tried by jury or by a judge where jury has been waived.

The system of appeals now prevailing in continental Europe bears a general resemblance to that of England and America. They also pass through a hierarchy of courts at the bottom of which there is usually a court of limited jurisdiction for the adjudication of comparatively unimportant cases, such as the *Juges de Paix* in France or the *Amtsgericht* in Germany. A court of general original jurisdiction, like the *Kreisgericht* of Austria or the Civil and Penal Tribunals of Italy, is established for the trial of ordinary litigation and is invested with appellate powers over the inferior tribunal. Next in order comes a court of the character of the *Oberlandesgericht* of Germany or Austria, the jurisdiction of which is chiefly or exclusively appellate. At the summit, with powers restricted to the correction of errors of law, is a supreme court, of which the *Reichsgericht* of Germany and the Court of Cassation of France and of Italy are types.

All final judgments and certain interlocutory orders and judgments of courts of inferior instance are everywhere subject to review by some superior tribunal. In criminal cases the review is usually confined to matters of law, as in Germany, Austria and Italy; only rarely, as in Switzerland, are the facts reexamined on appeal. Provision is ordinarily made for setting aside a conviction, on the showing of specified facts such as a later conviction of another for the same act which is irreconcilable with the first conviction, or conviction of a material prosecuting witness of perjury against the prisoner, or discovery of new evidence of a character to demonstrate the innocence of the prisoner, or, in a homicide case, the continued life of the alleged victim. Application therefor is

made in some places to the trial court; in others to the court of last resort.

The final judgment in a civil cause resulting from a trial in a court of first instance is reviewable on appeal. In most countries on such appeal both the law and the facts are tried: the parties are not confined either to the allegations or the proof offered or considered below, though generally no new claim or demand may be introduced. In Austria, however, the appellate court will not receive new matter except in explanation or refutation of the points of appeal. It may nevertheless cause the proof taken below to be amplified, and it may receive evidence offered and rejected below. No judgment rendered on appeal is subject to reexamination on the facts by a higher court. For instance, if the Landgericht of Germany renders a judgment on appeal from the Amtsgericht, its decision on the facts is final. All such judgments, however, as well as other non-appealable judgments, are subject to review for errors of law in the highest court of the land. In France and Italy the Court of Cassation, when quashing a judgment, cannot order final disposition but must send the case for retrial, not to the court which rendered the questioned judgment, but to another court of equivalent rank. This court is not bound to follow the decision of the Court of Cassation. If it refuses to do so, and the case again comes before the Court of Cassation for revision, it is heard by the full bench. If the full bench adheres to the decision on original revision, it remands the case to a third court of proper grade, which is required to make final disposition in accord with the opinion of the Court of Cassation.

As in former times, appeals still have administrative values quite apart from the necessity of securing justice to individual suitors. The first requisite of judicial social engineering is that the same factual situation shall uniformly create the same legal relations. The second is that this principle be effectually applied to litigation with a minimum of expense and delay and without discrimination. To effectuate these results there must be, for the formulation of non-legislative rules and the interpretation of legislative rules, a single authoritative tribunal which shall also either apply them or supervise their application to individual cases. For any such tribunal of manageable size to try all litigated questions of fact and law in a modern state would be a physical impossibility. Its function must be supervisory; the task of trial

must be assigned to inferior courts whose action shall be subject to correction.

The methods of appellate review current in the United States adequately secure the recognition of all rules thus established by the superior tribunal and their application both to the method of determining the facts and to the facts as found in the trial court. Uniformity and impartiality are to this extent attained. Delay and expense in the process have, however, not been reduced to a minimum. Though the general tendency is to disregard non-prejudicial errors, in some states there remains a disposition to reverse for mistakes the effect of which upon the merits is merely speculative and which allow an astute lawyer defending a bad case to exert himself in jockeying for points on appeal with which he can secure reversal in the appellate court and wear out the opposition. And constitutional provisions sometimes prevent desired expedition. The Federal Courts, under the Seventh Amendment, must order a new trial in reversing a judgment based upon a jury's verdict, even though the record clearly indicates which party must finally prevail. Still, as to matters of law the existing system is capable of functioning with reasonable efficiency.

As to matters of fact the appellate court necessarily has less control. On the one hand it may prevent the trial tribunal from avoiding the application of pertinent rules by making merely colorable or fictitious findings. A verdict or finding based on mere conjecture cannot stand. On the other hand it is impracticable for the court of last resort to retry cases de novo. Wherever such a plan has obtained, it has been vigorously condemned. It makes the first trial a pure economic waste, and results in a practical denial of justice to impecunious litigants. The original equity procedure, when applied to current practise, has at least two serious defects. First, it puts too great a burden upon the appellate court. A reexamination of all the evidence in every appealed case would overwhelm the justices. Second, it overlooks the impossibility of evaluating oral testimony by an examination of the printed page. And today much of the testimony in equity, like most of it at law, is presented orally. The present tendency is not to disturb the decree or order except where the original finding is rather obviously against the weight of the evidence. This furnishes a practicable means of counteracting local prejudice and idiosyncracies of particular judges.

But it cannot be used in those numerous cases where there is a constitutional right to trial by jury. Because of the accident of its composition or because of peculiar temporary local conditions, a jury may go badly astray on the facts. The prevailing corrective, a new trial granted in the discretion of the trial judge, is not sufficient, for he may himself be prejudiced or otherwise improperly motivated. The rule which makes his action non-reviewable, or reversible only for abuse of discretion, leaves open the door for fatal partiality and discrimination in the application of recognized legal rules. It is true that appellate courts have an uncanny way of finding errors of law on which to base a reversal when convinced that the result below is obviously wrong on the facts. But it should be unnecessary for them to resort to subterfuge. They have, and possibly should have, no power finally to determine the facts in such cases. But they should have the unquestioned right to require a new trial whenever for any reason they are convinced from the record on appeal that substantial justice has not been done.

APPLEGARTH, ROBERT (1834-1924), English trade union leader. By trade a carpenter, he was appointed (1862) general secretary of the Amalgamated Society of Carpenters and Joiners, which he rapidly developed into a union of foremost importance. He led the movement for full legalization of unions, and the evidence which he and other leaders produced of the efficient administration and moderation of the larger unions broke down public opposition. This opened the way for the act (1871) by which unions were legalized and their funds protected. He had a much wider conception of the

scope of trade unionism than his fellow unionists and was foremost in inducing the unions to take the important step of entering politics as a principal means of improving the workers' status. He supported legislation extending the franchise to the town artisan (1867) and providing a national system of elementary education (1870). In 1871 he resigned his general secretaryship as a protest against a too narrow interpretation of his duties by his executive. He entered commerce but continued his active interest in the workers' movement and lived to see trade unionism make great progress along the road which, in critical years, he had pioneered.

APPLETON, NATHAN (1779-1861), merchant and capitalist, the business genius of the American industrial revolution. His recognition of the necessity of systematic, double entry bookkeeping, his insistence on maintaining at least a third of a company's capital in liquid form for running expenses and his organization for mass distribution were largely responsible for the success of America's first large scale industry. He perceived and exercised the function of the promoter in assisting in the organization of most of the major Massachusetts textile corporations (*Introduction of the Power Loom and Origin of Lowell*, Lowell 1858).

Efficiency and sound policy formed the basis for his frequently expressed views on public questions. Regarding business as purely private, he opposed such government interference as the taxing of insurance companies and bank capital and the regulation of manufacturing corporations. He supported the tariff, however, as a constructive aid to industry, representing the Boston protective interests in Congress in 1831 and again in 1842 and defending the tariff of 1832, of which he was a principal author, in a famous speech against McDuffie of South Carolina (*Speech . . . in reply to Mr. McDuffie*, Washington 1832). He entered conspicuously into banking controversies, leading an attack in 1808 on the unsound Massachusetts country banks, supporting the Suffolk Bank system, advocating the monopolization of note issue by large banks and its limitation to a small proportion of their capital and insisting that specie payment be maintained at all costs (*Examination of the Banking System of Mas-*

sachusetts, Boston 1831). After striving to counteract the ill effects of Biddle's manipulation of the second United States Bank currency, he came to the conclusion that such a bank placed too much power in the hands of one man and should not be rechartered (*Remarks on Currency and Banking*, Boston 1841, 3rd ed. 1857).

In business methods and attitudes he was the prototype of the modern American capitalist promoter, but in his own mind he never ceased to be a merchant, proud of the liberal traditions of that ancient New England calling. In fact he combined in himself these two types, bringing the merchant's point of view to manufactures which had previously attracted only craftsmen and establishing business methods so modern that the textile industry has taken a hundred years to outgrow them.

APPOINTMENTS. With the expansion of governmental activities, the importance of the appointing power has naturally increased. An ever enlarging number of official relationships must somehow be established and appointment is the normal mode. In the United States the "more democracy" movement of the two middle quarters of the nineteenth century had spread the blighting and decentralizing influence of extensive popular election in state and local governments, but under the slogan of the "short ballot" reaction ultimately set in with the result that in some states and many cities the number of elected officers has been diminished in recent years. Fortunately the national constitution has from the beginning required that all officers beneath the president shall be appointed, and the difficulty of amending that instrument saved the executive branch of the federal government from the misguided fate that overtook the lesser units.

The power to appoint, coupled with the power to remove, is the quintessence of executive responsibility, but since it is peculiarly liable to misuse, checks are sought. The most important and the most far reaching of these is the merit system, with which we are not here concerned (see **CIVIL SERVICE**). In no country has that system been applied to all officers,

and especially have the directive officials of the upper grades been excepted. Even as to these, however, there are some checks on the executive power. For example, the United States Senate must ratify most presidential appointments. A somewhat analogous system spread generally, though not universally, in the state governments as the power of appointment passed from legislatures to governors, and a similar system was introduced at one time in many American cities. However occasionally valuable as a check on executive indiscretion, such a system has, generally speaking, produced more evil than good. It scatters and conceals responsibility; it promotes backstairs politics; it fosters unhealthy relations, sometimes amounting to bitter discord, between the executive and the legislative body. As applied to federal officers having local jurisdiction in the states, it amounts almost to a devolution of the executive power of appointment to individual senators or other politicians. Politics, operating through the medium of what is generally but not altogether accurately described as "senatorial courtesy," makes appointments a matter of local patronage. Although this system might be abolished root and branch by mere act of Congress (except as to judges of the Supreme Court, diplomatic and consular officers and heads of departments) there is small possibility of any such event. In no European country is anything comparable found.

In the states centralization of local appointments was not infrequent in the earlier days of the republic. But the spread of a thin population over a vast territory, apart from the individualistic spirit that indispensably accompanied the "rugged pioneer," led to decentralization. There have been recrudescences of central appointment since, prompted sometimes by local inefficiencies and scandals but quite as frequently by politics. A few states have eliminated senatorial confirmation of gubernatorial nominations, while a goodly number of cities vest the power of appointment exclusively in an elected mayor or in a city manager chosen by the council. Certainty of concentrated responsibility is preferred despite the risk of abuse.

Another restriction upon the appointing authority is the imposition of statutory qualifications for various offices. Such restrictions are by no means universal but they are sufficiently numerous, both in Europe and in America, to seem worth noting. They do not of course necessarily result in installing competent offi-

cers, but they often assist in preventing outrageously unfit appointments. A plumber cannot be made a legal adviser or prosecuting attorney; a butcher cannot be put in charge of engineering construction.

In the United States the qualification of residence in the state or local unit of jurisdiction—a qualification that is attached to many appointive offices—has been a serious handicap not only to the development of administrative efficiency but also to the development of careers in the public service. A large city may not take over at higher compensation an experienced and competent official in some smaller city. Nor may the states compete with one another for public servants. Even where the law does not expressly require residence, politics and custom often do. In the national postal service, for example, postmasters are never promoted from city to city. For many, if not for most, branches of the public service this requirement of residence is absurd. It prevails to a much smaller extent in European countries than in the United States, where there are, however, signs of its waning, especially noticeable in the fields of educational administration and city managership.

Another scheme for holding the appointive authority in leash is to place administrative services in charge of boards or commissions the members of which are appointed for relatively long and overlapping terms with varying degrees of protection against removal. The object is not only to secure continuity of policy but more especially to prevent the too active play of politics in appointing and removing officials. Although there has been some drift away from the board plan of organization toward the single headed office, this type of organization still prevails on a wide scale in many American states and in a considerable number of cities. In the national government it is found chiefly, although not exclusively, in those branches of administration that are vested with quasi-judicial powers. With the ostensible purpose of further lessening the force of party politics, membership in these boards is not infrequently required to be divided between the two major parties. The purpose is seldom realized. Bipartisanship does not often result in nonpartisanship. This is not surprising; for the requirement of party membership manifestly exalts party fealty and regularity above all other qualifications.

There are many critics of this board plan of

organization. Like the scheme of senatorial confirmation it obscures and weakens the responsibility of the appointing authority. Practise seems to justify its existence only when the functional nature of the administrative work to be done calls for collective rather than individual judgment and action.

Most of the countries of continental Europe stand in contrast to England and the United States in the matter of centralized control over appointments to offices of local jurisdiction. The highly centralized administrative systems of the Latin European countries place large political power in the hands of the central appointing authorities. Centralization of authority in the officials of Prussia and the lesser German states is almost as complete. In England there is relatively little appointment of local officers from London except in so far as strictly national services are concerned. In the United States every appointment in the national services is in theory centrally controlled; but such services are largely divorced from the spheres of action that are locally reserved. But even where appointments are made to the federal service, the process of appointment by "senatorial courtesy" sees to it that the appointees to local jurisdictional spheres are not merely parts of an inexorably pyramided hierarchy.

APPORTIONMENT, as now generally understood, particularly in American constitutional law, is a process of allotting representatives or

taxes on the basis of population. However, in the earlier stages of democratic government, representatives were usually apportioned on the basis of political units or corporate entities, or property considerations were allowed to count, as in the older European monarchies. Apportionment, too, was more occasional and less methodical than it is now.

The Constitution of the United States originally provided in Article 1 that representatives and direct taxes should be apportioned among the several states according to their respective numbers except that only three fifths of the slave population was to be counted. The "three-fifths" clause, which represented a compromise of the interests of the slave and free states, was abrogated, however, by the Fourteenth Amendment. But the further provision of the amendment for the proportional reduction of the basis of representation where the right of citizens might be in any way abridged has not been enforced against the southern states. The Sixteenth Amendment further abrogated the necessity of apportioning income taxes among the several states according to population. The other provisions of Article 1 have remained unchanged. Thus representatives and direct taxes, with the exception of income taxes, are apportioned among the states according to their respective populations. A census of the population must be taken every tenth year for use as a basis of reapportionment in the House of Representatives. The number of representatives cannot exceed one for every thirty thousand, but each state must have at least one representative. This provision has been based on the theory that the representative body should be a reflex of opinion throughout the country. The well known sectional problem prevented the application of the same principle to the Senate.

In the earlier state governments, representation in the lower houses was based largely upon geographical areas, such as the county, except in New England where it has been the town. In the upper houses, the basis of large single member districts formed by grouping or dividing counties has prevailed. This was not grossly unfair, because great inequalities in their populations did not exist. But the growth of urban centers has since changed the situation. The lower houses of Connecticut, New Hampshire and Vermont, and both houses in Rhode Island, are based upon town representation, and with the growth of cities this basis has

become highly unequal. In New Jersey the provision giving to the counties equal representation in the senate discriminates greatly against the larger cities of the state. The more common plan today is to provide for the periodical reapportionment of membership in the two houses upon the basis of population.

The first House of Representatives in the United States consisted of sixty-five members chosen from districts of approximately 30,000 inhabitants. Following the census of 1790, the number of representatives rose to 105 chosen from districts of approximately 33,000 inhabitants. Thereafter until 1920, following each decennial census, Congress undertook a reapportionment of the representation, increasing the number of members of the House of Representatives to 435 and the average size of the districts to 211,877. The constituencies are thus much larger than in England, where the ratio of representatives to population is one to 71,045, and in Germany, where the ratio is one to 126,854 inhabitants.

The actual districting of the states after a reapportionment is vested in the state legislatures. Until 1842, Congress left the states to their own devices in election methods, and representatives were often elected in the state at large; but the Apportionment Act passed in that year provided that the legislatures in each state should divide the state's territory into as many districts as there were representatives to be elected. These congressional districts were to be of "contiguous and compact territory containing as nearly as practicable an equal number of inhabitants," each district electing one representative. If, however, the state legislature failed to carry out this provision, some or all of the members might be elected at large on a general ticket. The practise of districting by the state legislatures has not been without evils, leading often to gerrymandering.

While it is easy to define apportionment as a process of allotment based on population, the application of the principle raises many difficulties of a mathematical nature in cases where the size of a legislative body for constitutional or practical reasons cannot be increased; this is true particularly in federal governments. If fractional voting were permitted in the legislative body, the exact number of representatives with whole votes, and the size of the fractional vote for an additional representative to which each state would be entitled in a theoretically perfect apportionment, could be readily cal-

culated. It would be necessary only to work out the following proportion: the number of votes for any particular state is to the total number of votes for all states as the population of the particular state is to the total population of all states.

If, however, this simple proportion were calculated, the result in nearly all cases would be that the number of representatives for each particular state would consist of a whole number and a fraction. Fractional voting, however, is not permitted. Therefore it is necessary to reach a solution of the apportionment problem in whole numbers. This fact alters fundamentally the mathematical nature of the problem. Even when the exact number of votes, including fractions, belonging theoretically to a state is precisely known, this knowledge is not of itself sufficient to determine the proper number of representatives to be apportioned to that state. The proper apportionment of integral numbers of representatives to a particular state may differ by several units from the number obtained by simple proportion. This is true no matter which of several known methods of apportionment is adopted.

There are five methods of apportionment which lead to a workable solution: method of smallest divisors, method of the harmonic mean, method of equal proportions, method of major fractions and method of greatest divisors. The first two methods tend to favor states having small populations and the last two methods tend to favor states having large populations. Political factors usually lead to considerable debate when a choice among these alternatives is involved. Apportionment may mean the abolition of the offices of some members. The desire to maintain sectional influences may also cause trouble.

The failure of Congress to follow the census of 1920 by a reapportionment, which caused much criticism, perfectly illustrates these considerations. Since the taking of the decennial census is mandatory, it was argued that Congress could neither postpone nor refuse a reapportionment. But population movements in the United States during the decade prior to 1920 created a difficult situation for Congress. The growth of population was very unequal. The steady flow of population from rural to urban districts was complicated by the removal of the textile industry from northern New England to the Piedmont sections of the South and the concentration of the automotive indus-

tries in Michigan with the consequent migrations of workers. The growth of New York City as a business center increased the population of New Jersey and Connecticut, where the rise of suburban towns was rapid. Likewise the migration from the Mississippi valley to southern California disturbed still further the equal growth of population.

Congress was confronted with a choice between two alternatives. Additional members could be granted to the House of Representatives, making that body more unwieldy and increasing the cost of government, or the House could continue with a membership of 435 and the seats be redistributed so that the representation would be equalized. The first alternative seemed undesirable because it would increase the unwieldiness of the House, and the second proved difficult of accomplishment. While eleven states would lose and eight states gain in representation, the reapportionment would for some members mean political retirement. In this delicate situation Congress refused to act. Members argued that the condition disclosed by the 1920 census was temporary, that the increasing concentration of population was due to the war, that this tendency would soon reverse itself, and that it would be unfair to the agricultural districts to carry out a reapportionment on the 1920 basis. It was even alleged that since the census of 1920 was taken during the winter months, when many country districts were difficult of access, it was not a proper enumeration. These purely rhetorical reasons for the failure to reapportion are insignificant beside the substantial fact that Congress was willing to apportion, provided that every state retain the number of members then sitting in the body, and that increases be provided in other states. In short, the real obstacle to reapportionment was the necessity of reducing the existing representation in some of the states, which made it impossible to agree upon the method of apportionment to be pursued, although the method of equal proportions was endorsed by the advisory committee to the director of the census and by a specially appointed committee of the National Academy of Sciences. Sectional feeling also intruded in a proposal aimed at the eastern states which represents an interesting addition to the Negro problem in apportionment: the exclusion of unnaturalized aliens from the number to be used as a basis of representation.

The agitation for reapportionment continued until in the special session of Congress called by President Hoover to meet April 15, 1929, a law was passed providing for the taking of the fifteenth census and subsequent decennial censuses and the apportionment of the membership of the House of Representatives according to those censuses. Reapportionment under this law will follow automatically on the census, with the number of members of the House fixed at 435. The president is directed to report to the short session of Congress, following the count, what the reapportionment would be according to two methods; one the method known as major fractions and the other the method of equal proportions. The first was the one employed in the last reapportionment. If Congress fails in the short session to enact legislation for reapportionment, the representation reported by the president automatically goes into effect in the election of the next Congress.

In European countries, historic associations have played a greater part in the creation of election districts. The distribution of seats is not always made periodically, and often only approximate mathematical equality prevails. European governments have also tended to adopt the principle of population as the basis of representative districts, but the wider adoption of proportional representation has complicated matters. Periodic apportionment is not required in England, but since 1865 representation in the House of Commons has on the whole tended to be apportioned in accordance with population densities. Constituencies of approximately equal size have replaced the former notoriously over-represented boroughs. In France a periodic redistribution takes place every five years. After experimenting with a system of geographical distribution upon which was superimposed a form of proportional representation France has since 1927 reverted to the old *scrutin d'arrondissement*. Germany follows the principle of population in fixing the number of votes in the Reichsrat and in determining the number of districts from which members of the Reichstag shall be chosen by a scheme of proportional representation. Most of the constitutions in the new states of central Europe, having adopted systems of proportional representation, provide for the distribution of seats to the several parties within each electoral area so that each party obtains one representative for every quota of

voters which it can rally to its support. All fractions of quotas are disregarded, but in the matter of establishing the electoral districts of constituencies it is uniformly the practise to consider the principle of population.

APPRECIATION is used in a variety of senses to refer to any increase in the value of a right, commodity or service. Variations of the concept seem to turn on two points—the time element and value meaning. Loosely and popularly it is used to describe price increases of relatively short duration, notably in the case of securities. Defined more strictly, the term denotes relatively permanent or enduring price increases of particular items or classes of property. It must be admitted, however, that the exact shade of meaning is variable and a matter of convenience to the user. The term is seldom used by theoretical economists, but it is found appropriate by many who deal with practical phases of the science. On the whole, however, it denotes price movements that outlast the business cycle or run counter to the downward swings of the price cycle. Or, more precisely, appreciation is an upward swing of the prices of particular rights, goods or services, after eliminating the effects of seasonal and cyclical factors and of the depreciation of the monetary standard.

At least two concepts of value—use value and exchange value—have been read into appreciation. Professor John D. Black, in analyzing the process of production, describes as appreciation an increase in the want-satisfying utilities of a commodity or an increase in the dexterity and experience of a human agent. His usage seems to be in harmony with that of wine makers whose product ripens with age or with that of engineers when they refer

to the seasoning and adaptation of a railway roadbed.

In contrast with this physical concept, the majority of writers identify appreciation with a concept of value derived from the market place. To the accountant appreciation of assets means the converse or offset to depreciation, in the economic not the physical sense. Likewise economists generally in referring to increments in the values of land, capital goods, money, securities or other economic goods contemplate potential or actual marketability at higher prices.

From the standpoint of an owner of property appreciation is based upon an increase in net earnings from use of property beyond the potential earnings discounted in the purchase price. In acquiring the right to appreciation when, as, and if it occurs, the purchaser ordinarily pays to the former owner some of the potential appreciation, in so far as the sale price exceeds an amount upon which current net earnings afford a competitive return. In other words, accrued appreciation and also a certain amount of unrealized and unaccrued but anticipated appreciation are normally discounted in the price of the property. Appreciation, therefore, is often conjunctural in nature; it may be accrued but not realized, and anticipated but not accrued.

The accrual of appreciation depends upon a reduction of costs, income remaining constant; or an increase in revenues, costs remaining the same; a more rapid turnover, the margin of net income remaining the same; or a decline in the rate of capitalization, net income remaining the same. Sometimes, however, the owner is not able to realize the accruing appreciation owing to use of the property at its existing capacity, or he may forego realization until sale of the property to another. The admission of non-owners to a share of prospective appreciation, as in the split of stock hitherto closely held, is customarily on such terms as will assure to current owners the realization of accrued appreciation and a certain proportion of the anticipated appreciation.

The distinctions between anticipated, accrued and realized appreciation direct attention to the limitations of the accrual of appreciation. In general these limitations are of three types, physical, legal and economic, and in any one item of property they may be combined and interrelated. For example, some commodities are more likely to appreciate than are others,

owing to peculiarities of the commodity itself. The durability of the good, the degree of mobility or immobility with respect to other goods or activities of men, are such factors. The degree of uniqueness, illustrated by pictures, rare books and personal services, is influenced by the physical composition of the good or nature of the service as well as their market position. Thus a great work of art may not be physically reproducible, but the possibility of appreciation is affected by the rise and fall of schools of art in popular favor. Expressed differently, appreciation is less likely to occur when goods or services are subject to competition with duplicates, easily and quickly made, or substitutes. Similarly when appreciation has been made possible by legal protection of certain privileges, the withdrawal or lessening of such protection, illustrated by the expiration of patents, tends to check appreciation. Moreover, effective public regulation of prices, as in public utility services, tends to curtail appreciation by limiting the net earnings which are its base.

The economic limits of appreciation may come from either or both sides of the old supply and demand formula. The popularity of an author or artist may decline; closely held stock may be split up and distributed to a wider public; sites in one locality may fall in value as new transportation facilities open up new territory. As Professor Black points out, "at any given time a piece of land may be either appreciating or depreciating; or it may be appreciating from one cause and depreciating from another."

Among the most important economic limits of appreciation is cost. This is frequently overlooked in the common statement that in a growing country the increase of population causes increased land values. Technological improvements check this tendency through their effects upon costs. Though averaging land values over a considerable area or comparison of widely separated years may disclose price advances in response to population growth, appreciation thus measured is apt to prove fictitious when costs are taken into account. Moreover, when the movement of land values is traced for smaller areas and intervening years, the price tendencies appear wavelike in both territorial and time dimensions, suggesting other influences than mere growth of population.

These influences are more apparent in con-

sidering particular tracts of land under single ownership. Whatever may be the course of land values generally, there is no assurance that a particular site will appreciate or depreciate synchronously. The accrual of appreciation of the particular site depends not only on the uses to which it can be put and the demand for those services but also upon the costs of putting the land to a given or new use and upon the cost of holding the land in present use until a new, more profitable use ripens. Generally speaking, the costs limiting appreciation may be described as the operating expenses incident to the existing use of the property and "ripening costs." The latter type of costs especially tends to rise as the demand for a site improves, with the result that these costs may drastically curtail the accrual of anticipated appreciation.

In considering the effects of appreciation, much depends on the point of view—whether that of owner, lessee, prospective investor, etc.—and on the uses of the appreciating property. If a commodity necessary to production appreciates, the effect is likely to be, to prospective investors or lessees, an increased cost of doing business, unless appreciation can be offset by economies in other directions; but existing owners or lessees may benefit from the appreciation. Similarly appreciation of consumers' goods, residential land, for example, tends to increase the cost of living, but the owner of such property may eventually benefit if he can realize the appreciation. Taking the price structure as a whole, if we eliminate business cycle and money standard appreciation, the effect of appreciation of some items of property ordinarily tends to be offset by declining prices of others.

One would suppose that appreciation would induce more efficient use of property. This indeed may be the result, but not necessarily so. A site may ripen to a higher use, commanding a higher price, if sold, but the more intensive or profitable use may be postponed because of inertia or because the site is encumbered with a structure that must be replaced at a cost which will wipe out the greater profits in the immediate future from the more efficient new use. In short, the more efficient use may not be economical when full consideration is given to costs.

This situation is more clearly seen in considering the effects of appreciation upon the problem of maintaining the investment. Many owners of real estate adopt the rule-of-thumb

principle of relying on the accrual of appreciation of the site to offset depreciation of the structures. That this is a perilous method of using appreciation is evident, for the appreciation of a particular site is uncertain in both amount and time of accrual; the rate of appreciation is variable; "the higher the ratio of improvement value to site value, the greater must be appreciation if it is to offset depreciation" and the smaller is the opportunity for appreciation; and the appreciation may be unrealizable, "unearning," owing to the cost of scrapping existing improvements of the site. Despite these uncertainties, the hope or the prospect of appreciation is an impelling factor in the distribution of investment funds.

Appreciation has also markedly influenced tax policies and tax programs. At the present time in the United States, accrued appreciation of land is taxed by the federal government as a capital gain at a rate of $12\frac{1}{2}$ percent in the year in which it is realized. Moreover the general property tax based on assessed sales values frequently takes part of the appreciation as it accrues but before it is realized. Finally the taxation of bare-land values, as sponsored by Henry George and his followers, is a proposal to take all appreciation of that form of property, or at least more than is taken by existing taxation.

Appreciation complicates the problems of cost analysis, especially in price regulated industries. The value at which land should be included in a rate base illustrates the problem, though similar difficulties are met in treating appreciated securities in a rate base, as in Massachusetts. Considerable areas of land for, or adjoining, railroad rights of way have been acquired by gift or sale at low prices and have risen greatly in value, partly as a result of the utility's services in developing the community. Should such land be carried in the rate base at its original cost to the utility, at its present appreciated value or at some figure between the two extremes? The general practise is to allow the utility owners to retain at least some of the appreciation, recognizing, however, that first, not all the appreciation is attributable to the utility's efforts, and second, appreciation of the right of way measured by the values of adjoining tracts is partly unrealizable and "unearning," even if permission to sell the right of way were granted. Strict adherence to the cost basis of land valuation, omitting all appreciation, is confiscatory under the federal

constitution as interpreted by the Supreme Court in the *Minnesota Rate Cases*, 230 U. S. 352 (1913).

APPRENTICES, STATUTES OF. See LABOURERS, STATUTES OF.

APPRENTICESHIP is a method of passing on acquired trade skills and of maintaining a supply of craftsmen. It is a mutual relationship under which a novice, who is generally a minor, is taught the art of a trade by one who is engaged in it. The apprentice in return pays either in whole or in part for this instruction by work on objects destined for consumption or sale by the master.

Contrary to the usual impression, apprenticeship did not originate in the Middle Ages. The Babylonian Code of Hammurabi makes explicit provision that artisans shall teach their handicrafts to those sons whom they may adopt, and that if this is not done the boys may return to their fathers' houses. Not only was apprenticeship thus legally regulated at this early date but the relationship between master and apprentice was modeled upon that of father and son. The records of Egypt, Greece and Rome show that apprenticeship was an integral part of the industrial systems of those cultures. Nor has apprenticeship been confined to the Occident. It is still the predominant means of learning a handicraft in the Orient, and is there regulated by the guilds in much the same manner as by

the European guilds during the mediaeval period. Such a system is in fact an inevitable feature of handicraft production since the growth of industry very frequently exceeds the ability of a craftsman's family to man it. Other boys must be taught the trade in order to provide a sufficient supply of skilled craftsmen and to insure continuity of management.

The respective rights of apprentice and master were generally stated in an indenture signed not only by these two parties but also by the parent or guardian of the apprentice. The period of time prescribed for apprenticeship by the mediaeval guilds and provided for in the indentures varied quite widely. In France it usually ranged from three to five years, but in England seven years was the more common term.

In addition to training, the masters generally furnished board and lodging to the apprentices and agreed to supervise their morals and habits. The apprentices on their part agreed faithfully to serve the masters, and in some cases their families agreed to give payments in cash or in kind as an added compensation for the training furnished. The master was given the power to discipline the apprentices, but the guilds and the civil authorities were empowered to supervise the relations between them and to protect the apprentices from abuse.

As long as handicraft production was carried on in small units, the relationship between apprentices and masters was intimate and promotion into the ranks of the masters was fairly certain after the service of an intermediate period as journeyman or *compagnon*. The number of apprentices who could be trained was limited by the guilds in order to protect the masters from the severe competition which would necessarily result from the presence of large numbers of trained craftsmen. The period of apprenticeship was also probably longer than was required to master the trades of the time; by these methods something of an artificial monopoly was maintained by the town workers which enabled them to raise the value of their goods in comparison with those of the countryside and thus obtain a differential advantage over the agricultural population.

As the size of the producing unit increased, the lot and prospects of the apprentices became much less favorable. The masters were more likely to be merchants, capitalists and employers than fellow craftsmen. Not only was personal contact between the two groups lessened but entrance into the ranks of the masters was made

increasingly difficult for the rank and file of the apprentices. This was caused in part by the increasing amount of capital needed to purchase the raw materials and to set up a shop and in part by the policy of the more well-to-do masters, and of the guilds which they had come increasingly to dominate, to erect artificial barriers. Although sons of masters were quite generally admitted to the upper ranks without having served the full term of apprenticeship, others were required to pay large fees in addition, and the actual numbers who were thus taken in came to be more and more restricted. All these factors increased the ratio of journeymen to masters. It had then become advantageous for the masters to increase the number of the apprentices, since a large supply of the latter could be used to lower the wages of the journeymen and thus to increase the employers' profits. The journeymen in self-protection frequently shirked teaching the apprentices the full secrets of the trade. With the increasing splitting up of crafts the apprentices suffered further hardships, since they were compelled to serve the same length of time as before, although less time was actually required to learn the processes.

Although the regulation of apprenticeship originated in the guilds, with some municipal supervision, France and England developed also a system of national regulation. The Statute of Artificers, enacted by Elizabeth in 1562, nationalized the provisions of the London craft guilds which permitted only householders to take apprentices, required a minimum period of seven years and fixed twenty-four years as the minimum age at which the apprentice could come out of his service. In order to check the drift of labor to the towns, to preserve the privileges of the townsmen and to insure a plentiful supply of agricultural labor for the landlords, it was provided that only the sons of townsmen might be apprenticed to craftsmen within a particular town. Some of the more lucrative trades, such as those of merchants and goldsmiths, were reserved for the children of propertied persons. The enforcement of this statute was in the main entrusted to the guilds and municipalities, and with the decay of the guild system, due to the increased practice of trades by non-members, and with the rise of new industries, it gradually became obsolete.

Apprenticeship was, however, also used in both England and America as a means of poor relief for children who were charges upon the community, although the poor law authorities

were in general more concerned with getting the children off their hands and having them maintained than in making sure that they were adequately taught a trade. While the apprenticeship system, as a method of caring for children who were a state charge, produced flagrant evils, it was a step in advance of herding them in general mixed workhouses with paupers of all ages and classes.

With the advent of the factory system, involving still further subdivision of labor and the development of automatic machinery, the amount of technical skill required of the artisans was appreciably reduced, and youthful and untrained workers were brought into the crafts in increased numbers. The hand workers, in order to protect themselves against this new competition, sought to have the law enforced and extended to the new trades, but instead the House of Commons in 1814 repealed the act. In France the guilds had been legally abolished during the revolution (1791), and although a law regulating apprenticeship was passed in 1851 it was virtually ineffective. Germany, Austria and a number of other European countries instituted a more thorough legal regulation of apprenticeship; but despite these efforts, as the factory system continued to replace the handicrafts and as large scale production became more general, apprenticeship necessarily declined. The principal reason for this decline was the reduction in the amount of skill required of the great mass of the workers, rendering a prolonged period of training unnecessary for all save a small proportion of engineers, designers and similar highly skilled persons. But while this latter group needed much greater skill than the craftsmen of former times, their work became so complicated and technical that it could not be mastered by the old method of learning on the job. Schools of engineering and of other applied arts and trades were established to furnish that basic training in mathematics, chemistry, physics, etc., upon which so much of modern production rests.

In occupations which remain on a primarily handicraft basis, particularly in the building trades and in machine repairing, or in industries where production is unstandardized and varies appreciably from unit to unit, as in custom tailoring, pattern making and some molding and printing work, or where the responsibility for machines and lives is great, as is the case in engineering, a considerable period of practical preparation is needed at the job itself. Here

apprenticeship remains, although in a diminished form from that which formerly prevailed. But the custom of domiciling apprentices with the employers disappeared in western Europe and America during the nineteenth century because of the increasing size and the increasing impersonality of industry. The former provision of board and lodging was then commuted by the employers to the payment of a small monetary wage which was generally graduated according to the length of time which an apprentice had served.

In some of the trades there has been actual difficulty in securing an adequate number of apprentices. This has been caused in part by the restrictive policies of a few of the trade unions of skilled workers in the United States and Great Britain, where a rather rigid limitation of the number of apprentices and a prolongation of the period of apprenticeship beyond that required to attain competence have served to reduce the numbers below what they would have been had free competition prevailed. This has in turn maintained the wages in these trades at a higher level than would otherwise have been the case. But that these restrictions have seldom been the main cause for the paucity of apprentices in these trades is demonstrated by the fact that the employers have almost universally not availed themselves of the privilege of accepting as many apprentices as has been permitted by the union rules and that this failure to absorb the union maximum is almost as characteristic of non-union as of union establishments. There are several more fundamental factors which limit the effectiveness of apprenticeship in these trades. First, there is the reluctance of the employer to go to the expense of moving the apprentice about from job to job when there is no surety that he rather than another employer will be able to reap the benefit of an apprentice's skill once the latter has become a journeyman. The freedom of an apprentice to transfer his services to another employer when he has completed his term of apprenticeship therefore causes employers to depend more on hiring apprentices away from other employers than on training them, but this policy when generally pursued obviously defeats itself. A second factor is the common reluctance of journeymen to train the apprentices adequately since they do not wish to raise too many competitors for themselves. Finally, because the apprentice's wages during most of the period of his apprenticeship are lower than those which he could

receive as an unskilled worker, there is a strong temptation for children to avoid the apprenticeship openings in order to obtain the immediately higher earnings.

In recent years efforts have been made in the United States, most notably in the printing and building trades, to put apprenticeship training on a firmer footing, and joint committees of employers and unionists have been formed in a number of cities, notably New York, Chicago, Cleveland and Niagara Falls. Indentures are drawn up specifying the types of training to be given and the length of time to be devoted to each, an interchange of apprentices is provided if full or adequate training cannot be furnished by a given employer, the apprentices are given instruction in special classes, and in some cases special supervisors have been appointed to stimulate the system and to inspect the work done and training offered, while diplomas are granted to those who satisfactorily complete their work. The International Typographical Union also has prepared an excellent set of correspondence courses which are widely used by apprentices in union printing shops. The state of Wisconsin also has created a position of supervisor of apprentices, who works under the state's Industrial Commission and whose duties are similar to those outlined above.

During the last half century efforts have been made to provide for the vast majority of juvenile workers who are employed at unskilled jobs and who are not apprenticed some form of public instruction and supervision analogous to that afforded by the apprenticeship system in its more favorable aspects. The most important development along this line has been that of part time continuation schools where employed juveniles are given training a few hours each week, out of their working time, not only in the work in which they are engaged at the time but also in work which they hope to do and in general preparation for citizenship and life. There has also been an appreciable extension of vocational guidance to enable children to select the lines of work which they will enter with a better knowledge of the opportunities that are open to them than was formerly the case.

APPROPRIATIONS. See BUDGET; PUBLIC FINANCE.

AQUINAS, THOMAS (c. 1226–74), scholastic philosopher. He was born near Aquino, in the territory of Naples, of a distinguished noble family, entered the Dominican order at sixteen and studied at Cologne under Albertus Magnus, subsequently following his master to Paris. He taught philosophy and theology at Cologne, Paris and various places in Italy.

The political, economic and social doctrines of St. Thomas exemplify two general characteristics of his writings: acceptance, so far as it was consistent with Christianity, of the philosophy of Aristotle, and systematic presentation of the traditional Catholic teaching. Following Aristotle, St. Thomas held that men are impelled to live in society by their needs of life and development. Although it is not the earliest nor the most spontaneous form of association, the state is nevertheless universally necessary. Civil authority derives ultimately from God and ordinarily becomes lodged in particular persons through the consent of the people. Although the subjects owe loyalty and obedience to the legitimate ruler they have the right to resist, both passively and actively, a government that has become gravely and incorrigibly oppressive. The ideal form of government is a combination of monarchy, aristocracy and democracy. The monarch should preferably be elected, the aristocracy should consist of picked men chosen by and from the people, and all the citizens should have some share in the government.

Civil society functions primarily through legislation. Law in the true sense is an ordinance of reason for the common good. Hence civil

statutes have no moral validity when they are contrary to the natural law. The common good means not only the public welfare, as a whole, but the well-being of all classes and even of all individuals, in due proportion. Welfare comprises goods of the mind and soul, goods of the body and goods of fortune. Peace, health, natural beauty, labor, commerce, education and virtue are all proper objects of civil legislation. However, the state cannot wisely attempt to suppress all sin, but only those grave offenses which injuriously affect society. When the ordinary sources of public revenue do not provide sufficient funds, the rulers are justified in levying taxes upon their subjects, but not for their own avarice nor in greater amount than is required by the common welfare.

The state exists for the individual, and not vice versa, and for all individuals, since all are persons and are equally endowed with certain natural rights. According to Aquinas, however, slavery is in accord with the natural law because it is better for some men, and for society, that they should be under economic domination. It is uncertain whether St. Thomas meant to apply this principle without qualification to the serfs of his own time in Europe. At any rate he declared that since all persons are by nature equal, the slave has certain natural rights which the master may not violate; for example, the right to life, sustenance and normal family relations.

In his economic as in his political doctrines St. Thomas is representative of mediaeval thought. While private property is in accord with, it is not absolutely required by, the natural law. Nevertheless it has been proved necessary by the experience of all peoples. Ownership should be private, but the use of goods should be common so that they may be readily shared with the needy. Trading is morally lawful if directed to lawful objects; for example, when the trader seeks moderate gain as a means of livelihood or in order to assist the poor or for the public good, and when he regards the gain not as an end in itself but as the reward of labor. In the second place, merchandising should be honest in its methods. The just price can be established through public regulation, custom or the judgment of upright men. Taking interest on loans is unjust because it is an attempt to sell the same thing twice, that is, to exact payment for a use which is inseparable from the thing used. Since it passes from the borrower at its first use, money loaned is

in reality money sold. Any gain made by the borrower is the fruit not of the loan but of his own industry. The only recognized titles to income are labor and risk. The sole specific reference which Aquinas makes to wages is that they are subject to the same rule of justice as prices. And it may be assumed that he accepted the current principle of his time, that the just price of goods would always enable the producer to live in conformity with the customary standard of his class.

An important social conclusion which Aquinas drew from the principle of common use was that a man's superfluous goods or income are due by natural law to the needy. Poverty is undesirable because it is the occasion of many sins. Both state and church should strive to provide such conditions of family life that children will be born with sound bodies. Education is essential to the welfare of the individual and of the state. It comprises training of all the faculties in due proportion, which means that greater attention should be given to the soul than to the body. So far as necessary it should be fostered by legislation. Birth control is against nature and therefore morally wrong, and divorce is wrong because it is harmful to the children and to society and forbidden by the words of Christ. Woman should be subject to man because the latter possesses "greater discretion of reason."

The authority of the works of St. Thomas among Catholics is far greater than that enjoyed by the social teachings of any other writer, especially since they were commended by Pope Leo XIII in his encyclical *Aeterni patris*, August 4, 1879. Recently there has been an active revival of interest in his philosophy—a neo-Thomist movement—which has had some currency throughout Europe and especially in the French speaking countries, where the works of Cardinal Mercier, Étienne Gilson and Jacques Maritain are representative of it. A growing dissatisfaction with the dominance of empiricism, a desire for the fixity and clearness of scholastic philosophy and a hope that in it will be found a guide for the vexing problems of modern life have been among the factors contributing to this revival.

ARABI, AHMED (1841-1911), Egyptian nationalist leader. He was the son of a village sheikh in the Nile delta. He received a smattering of education at El Azhar University in Cairo, was conscripted into the army and soon became an officer. He was not a very capable soldier but he made his mark as an orator and a "barrack-room lawyer." In the troublous times at the end of the seventies he voiced the discontent of the army and especially of the native Egyptian officers, who were bitterly hostile to the Turkish ruling caste. In 1881 he openly and successfully defied the khedive, and before long was made minister of war. In June, 1882, the general disorder and agitation led to a massacre by the mob in Alexandria and the bombardment of the city by British warships. The khedive was now a mere pawn and Arabi, at the head of the army, appeared to be the master of Egypt, menacing the foreigners as well as his enemies at home. Within a month or two, however, a British force under Wolseley completely routed the Egyptians at the battle of Tel-el-Kebir, and Arabi was taken prisoner. He was tried by court martial and condemned to death, but at the instigation of the British government the sentence was commuted to perpetual exile in Ceylon. He was allowed to return to Egypt in 1901 and remained there until his death in 1911.

Arabi was not the stuff of which great leaders are made. He was a simple minded and ignorant man, an honest and zealous patriot, but weak in judgment and action. His revolt was not, as it was generally regarded at the time, a mere military rebellion. It was a genuine, though

premature and abortive, movement of nationalism, and was widely supported by the Egyptian people. Modern opinion criticizes Gladstone's government for misreading the situation in Egypt and the motives of the "rebels." A more far sighted statesmanship might well have backed Arabi and made him a partner with Great Britain in the rehabilitation of Egypt.

ARAI HAKUSEKI (pseudonym of Kimiyoshi) (1657-1725), Japanese scholar and statesman. Hakuseki was a product of the era of Genroku (1688-1704), the heyday of art and culture of old Japan. He was born of a *samurai* father, impoverished and obscure, but distinguished himself as a Confucian scholar and was appointed tutor to the lord of the province of Kōfu, who in 1709 became the sixth shogun under the name of Iyenobu. Invited to accompany his illustrious pupil to Yedo (Tokyo), the seat of the shogunate, and as official lecturer and trusted counselor to the new ruler of Japan, Hakuseki came to occupy a position of high honor and commanding influence, which he continued to hold during the brief rule of the seventh and infant shogun, Iyetsugu (1713-16), son of Iyenobu. During these few years under the two shoguns Hakuseki carried out a number of reforms. It was his sound practical sense that enabled him to combat successfully a proposal to debase the currency, or to regulate the foreign trade at Nagasaki so as to curtail the outflow of gold and silver. But, on the other hand, his punctilious notions of Confucian propriety led to unnecessary elaborations of etiquette and ceremony which were not relished by the seventh shogun. Arai retired and wrote in 1716 his memoir, *Oritaku Shiba No Ki* (In the Hour of Burning Faggots), a unique piece of autobiography in Japanese literature.

Hakuseki was a voluminous writer with more than 170 works to his credit, of which *Hankan Fu* (Annals of Feudal Houses, 30 vols., written 1701), *Koshi Tsu* (Through Ancient History) and *Tokushi Yoron* (Gleanings from History, written 1712) constitute his lasting achievements from both scholarly and literary view-

points. He has left a few books, including *Seiyo Kibun*, on western countries and civilization, of which he learned from a Jesuit missionary, Father Sidotti, brought to Yedo as prisoner.

ARANDA, PEDRO PABLO ABARCA DE BOLEA, CONDE DE (1718-99), Spanish soldier, diplomat and statesman. For a time he served his country in the office of ambassador at the court of King Augustus III of Poland. On his appointment by Charles III of Spain as president of the Council of Castile—then the supreme consultative body of the monarchy—he began his career as head of the government. He was an enthusiastic admirer of the *encyclopédistes* and of their doctrines, and promulgated the famous decree of February 27, 1767, expelling the Jesuits. Aranda's anti-English policy impelled him to favor actively immediate recognition of the independence of the United States. As Spanish ambassador at Paris (1773-87) he was a partisan of the revolution; and when he became president of the Council of Castile for a second time in 1792, his prorevolutionary sentiments incurred the enmity of Godoy, the favorite of Charles IV, and resulted in his removal from office in the same year.

Aranda's views on internal colonization are of great interest to students of the social sciences. His principal measures in this regard are the royal decrees of May 26, 1773, and of May, 1793, which may be summarized as follows: national, municipal and uncultivated lands were made subject to colonization and distribution (this ruling, however, not to apply to certain portions of municipal land set aside as a commons for all the inhabitants); lands were granted in emphyteusis (perpetual lease) on condition that they be maintained in cultivation and that the canon fee be paid, and were distributed on the basis of the number of yoke of oxen at the holder's disposal; the decree of 1793 declared

that uncultivated land belonged to him who cleared it; colonized lands were to remain exempt from all taxation, even the church tithe, for ten years, and from the canon fee for fifteen; sublease or transfer to foreigners was prohibited. While these laws had little effect on the actual situation of land tenures in Spain itself, the ideas involved have played an important part in the development of conceptions of land tenure in Spanish America, notably in Mexico.

FERNANDO DE LOS RÍOS

ARBEITSGEMEINSCHAFT has been used in German speaking countries to designate various forms of association among people working for a common end. In the recent and technical sense *Arbeitsgemeinschaften* are voluntary joint associations of employers and employees for regulating industrial conditions. Such associations appeared before the war, but the industrial truce which followed the outbreak of hostilities gave a great impetus to their spread. By 1915 there were nineteen local associations in various industries. On November 15, 1918, an agreement was concluded by the national centers of the trade unions and of employers' associations which provided for the establishment of the Zentralarbeitsgemeinschaft in order to facilitate "joint dealings with all the economic and socio-political questions concerning German industry as well as with all legislative and administrative matters pertaining thereto." The organization was not actually set up until late in 1919; associations of the same type were organized later in various regions and industries. At the time great hopes centered in these organizations, but in spite of some achievements they were not justified. Contributing causes for failure may have been that German industry was already largely organized in other directions, that the bureaucracies of the older organizations were often not favorably disposed toward the *Arbeitsgemeinschaften* and that the introduction of radical and political aims necessarily limited their possible effectiveness. Moreover the splitting up of the German trade unions into groups that were oriented on the basis of their social philosophy interfered with the *Arbeitsgemeinschaften*. The Zentralarbeitsgemeinschaft was dissolved by the withdrawal of the central trade union

executive in 1924, and the local associations followed suit.

The organization of *Arbeitsgemeinschaften* was the expression of a tendency to mitigate opposition between capital and labor and to bring about their collaboration for common ends. These organizations were not the sole manifestation of this tendency, nor was the latter limited to Germany. It is interesting, however, that the term *Arbeitsgemeinschaft*, when related to Tönnies' distinction between *Gesellschaft* and *Gemeinschaft*, implies an inner organic union, far beyond mere association. In a sense the use of this term suggests a reversion from the Marxian insistence on the reality of class divisions, a recognition of organic ties between the various elements of the industrial structure.

In contemporary Germany *Arbeitsgemeinschaft* has become a very popular name for loose associations with the most varied aims in all possible spheres of social life. When people unite for specific purposes, without regard to party or religious divisions, an *Arbeitsgemeinschaft* is now founded in preference to a *Verein*. The word is used for professional associations and suggests a guaranty that the organization will include only those trained in the field. Even the German and Austrian associations founded to work for the union of the two countries call themselves the German-Austrian *Arbeitsgemeinschaft*.

Consult: Lederer, E., and Marschak, J., in *Grundriss der Sozialökonomik*, vols. i-ix (Tübingen 1914-29) vol. ix, pt. ii, p. 237-40, and bibliography given there, p. 232-33.

ARBITRAGE may be defined as the practise of buying a given security or commodity in one market and almost simultaneously selling it in another market with a view to profiting by the difference between the purchase and sale prices. It has its basis in the fact that at a given time securities and commodities often happen to be selling at different prices in various markets. The practise exists in many markets, such as stock and bond, organized produce, marine insurance, money and foreign exchange markets. Most commonly, however, arbitrage refers to the practise in the security, produce and foreign exchange markets.

In the security and produce markets arbi-

trading may be either "domestic" or "foreign." With respect to the former the process is relatively simple. Assuming the necessary equipment for the speedy transmission of orders and their prompt execution in both markets, the arbitrager simply buys in the low market and sells (often in the form of a short sale) the same amount in the high market. Settlement may be made either by shipping the security or commodity purchased, or by reversing the purchase and sale should the quotations in the two markets at some later time stand in a different relation to each other than was the case when the two original transactions were entered into.

In foreign arbitrage the process is more complicated, as may be illustrated by arbitrating between the New York and London stock exchanges. Here speedy communication is not the only requisite. Numerous factors must be taken into account, such as stamp taxes, interest charges, cable tolls, insurance and shipping expenses, foreign settlement systems as contrasted with our own daily settlement, rates of foreign exchange and different methods of quoting prices. The last two factors are especially vital (foreign exchange rates fluctuating continually and London security quotations being given on the arbitrary basis of \$5.00, instead of \$4.8665, to the pound sterling) and compel the speedy reduction of London and American quotations to a mathematical parity in order to justify opposite transactions, as the margin of profit is usually small. To close the transactions the securities may be shipped from one market to another, but this is avoided, if possible, because of the expense involved.

The pressure of buying in the low market and selling in the high soon tends to level prices in all the markets the world over. A security is thus said to have approximately one price everywhere. The action of numerous arbitragers also tends to make the market more continuous for other buyers and sellers than would otherwise be the case. As between foreign countries arbitrating also facilitates the settlement of international debts, most foreign arbitragers resorting to the practise for this special purpose. In the commodity markets, besides leveling prices and rendering the markets more continuous, arbitrating directs the flow of grain, cotton, etc., from places where the supply is too plentiful to those where the demand is greater, thus assuring an adequate

distribution of our staple commodities among all communities.

Through arbitrating, foreign exchange dealers also bring the rates for cables in different markets (as, for example, sterling cables in New York and dollar cables in London) into proper harmony whenever they may diverge from their equivalent quotations. The business is conducted by two parties, each in a different market, with a view to having their transactions offset each other. Both will buy cables should the two market rates appear too low. Each will thus receive a cable transfer from the other and thereby obtain the funds necessary to meet his expenditure for the purchase. The gross profit of the two arbitragers, cooperating for a mutual profit, represents the amount by which the cables diverged from their equivalent quotations. Should the cable rates appear too high, each of the arbitragers will sell a cable drawn on the other, and will then satisfy the other's order with the proceeds obtained from his own sale. As in this illustration of two markets, so quotations in three (or more) markets have a point of equivalence. Thus a foreign exchange dealer with business connections in all the markets under consideration may, with sterling rates higher in New York and lower in Paris, derive a profit by selling a sterling cable in New York and covering the same in London through the purchase of another sterling cable in Paris.

G., *Organized Produce Markets* (London 1922) ch. v.

ARBITRATION, COMMERCIAL, is the process by which business men submit disputes which arise out of their business transactions to one or more persons whom the parties select to decide their particular case. It is a substitute for court litigation. The process is based either upon a clause inserted in a more general contract whereby the parties thereto agree to arbitrate disputes which may arise between them in the future in connection with the general

contract, or upon a contract to submit an existing controversy to one or more arbitrators. The first type of arbitration agreement is called a future-disputes clause; the second type is known as a submission agreement.

The modern development of commercial arbitration in the United States relates chiefly to its use by trade associations and chambers of commerce. Since about 1920 these organizations have incorporated future-disputes clauses into their articles of membership, by-laws or standard contract forms. Their members thereby agree in advance to arbitrate disputes which may thereafter arise between them in their mutual dealings. On January 1, 1928, more than one hundred and fifty national or interstate trade associations had adopted this policy. Similar development has taken place in chambers of commerce and local business men's organizations. This use of future-disputes clauses distinguishes the modern practise of commercial arbitration from its earlier use. Formerly parties ordinarily entered into an agreement to arbitrate only after a controversy had arisen between them. The modern practise of commercial arbitration by American associated business has its precedent in the practise of the trade associations and chambers of commerce of England and the continent. It is correlated with the practise of those countries through the United States Chamber of Commerce, the International Chamber of Commerce, and trade associations with American and foreign members who are engaged in foreign commerce.

The rapid and extensive development of this modern practise is largely due to conditions which surround court litigation. Congestion of trial court calendars has been a factor. Capital is thereby unduly tied up, bankruptcies intervene and witnesses forget, die or move away before the case is tried. The records of a case are promiscuously published, to the prejudice of the credit and trade reputation of the parties. When the date for trial finally arrives, there is frequently delay in proceeding with the case, even if one or more continuances are not granted. The jurymen have often had little experience and no training in the business out of which the particular case arises. Judges are likewise frequently unqualified to try the highly technical matters involved in modern business controversies. Trial court practise seems technical and treacherous, and tends to involve unnecessary bickering. Complex rules of pro-

cedure and of the law of evidence, as well as the practise of opposing attorneys to assume no common responsibility with the trial judge to keep the case free from legal errors, often enable the losing party to appeal the case and to procure a reversal and a new trial, with delays and expenses repeated.

Commercial arbitration, on the other hand, contemplates that the parties to a dispute shall choose one or more persons specially qualified to decide their particular case. There are no pleadings. Each party may tell his side of the case and present his testimony and other evidence informally. An arbitral hearing is held in private and at such time and place as meet the convenience of the parties and arbitrators. Experience teaches that an arbitral adjustment of a business dispute leaves the parties susceptible to further business dealings. What is more significant, the use of future-disputes clauses often induces the parties to resolve their own misunderstandings before they require a formal arbitration.

Commercial arbitration in its modern phases has called for legislation which will give new legal effect to arbitration agreements. Common law rules give little effect to such agreements. The courts have held that future-disputes clauses and submission agreements are revocable; that is, that a party to either type of arbitration can maintain an action in court although he has agreed to arbitrate the dispute upon which the action is based, and that either party has the power to revoke his agreement by notice, even after arbitrators have been appointed, provided it is given before an award is rendered. Courts of equity have the same rules of revocability. Furthermore, they will neither decree specific performance of arbitration agreements nor appoint arbitrators when a party refuses to nominate them. Under common law rules an award can be enforced only by an action in court based upon the award.

In 1920 the New York Legislature enacted a new arbitration law which abrogates these common law rules of revocability of written agreements to arbitrate. It provides a summary procedure to enforce specifically those agreements, including appointment of arbitrators by a court in default of action by one of the parties. Awards can be enforced summarily by motion to a court. New Jersey, Massachusetts, the Territory of Hawaii, Oregon, Pennsylvania, California and Louisiana have enacted similar statutes since that time. The United States Arbitration

Act also has like provisions with respect to agreements to arbitrate disputes arising out of transactions in foreign and interstate commerce. A more limited statute has been submitted to the legislatures by the National Conference of Commissioners on Uniform State Laws. This new legislation has received the support of leading American lawyers as well as business men. The United States act was drafted by the Committee on Commerce, Trade and Commercial Law of the American Bar Association and was approved by that association. The Commercial Law League of America, another national organization of lawyers, has formally resolved to aid in procuring the enactment in each state of an arbitration statute patterned after the United States act. The State Bar Associations of New York, New Jersey and Louisiana were also especially active in procuring the adoption of the new arbitration laws in their respective states.

WESLEY A. STURGES

See: COMMERCIAL LAW; COURTS, COMMERCIAL; COURTS; REMEDIES, LEGAL; PROCEDURE, LEGAL; CHAMBERS OF COMMERCE; TRADE ASSOCIATIONS; BUSINESS ETHICS.

Consult: *Selected Articles on Commercial Arbitration*, ed. by Daniel Bloomfield (New York 1927); American Arbitration Association, *Year Book on Commercial Arbitration in the United States*, vol. i (New York 1927); *Internationales Jahrbuch für Schiedsgerichtswesen in Zivil- und Handelssachen*, vols. i-ii (Berlin 1926-28); Sturges, W. A., "Arbitration Under the New Pennsylvania Arbitration Statute" in *University of Pennsylvania Law Review*, vol. lxxvi (1928) 345-93, 498-547, and "Arbitration Under the New North Carolina Arbitration Statute—The Uniform Arbitration Act" in *North Carolina Law Review*, vol. vi (1928) 363-427; Bacon, Roger S., *Commercial Arbitration as Governed by the Law of England* (London 1925); Birdseye, Clarence F., *Arbitration and Business Ethics* (New York 1926).

ARBITRATION, INDUSTRIAL, is the process of referring disputes between employers and employees to the decision of "impartial" adjudicators. It differs from ordinary collective bargaining (sometimes called conciliation) by its use of outsiders not parties to the dispute. It differs from mediation (also frequently called conciliation) in that these outsiders are called upon to make the actual decisions instead of merely using their good offices to bring the contestants to an agreement.

Arbitration is of two main types and owes its growth to two lines of development. In the one case, voluntary arbitration, the parties directly concerned decide to appeal to an arbitrator's

judgment as a supplement to their ordinary bargaining practises. In the other case, compulsory arbitration, the movement typically begins outside industry, and the contestants are, if necessary, forced to arbitration by the power of the state. The former practise is of long standing and has been widely used in many countries. Very frequently arbitration is the tactical plea of the weaker party, but time and again it has appeared to be a real convenience to both contestants as a way of ending or averting costly strikes and lockouts. In a number of cases, moreover, it is used not merely as an occasional recourse but as a permanent part of the bargaining machinery. It has particular advantages in the interpretation and application of a collective agreement already in force. More rarely it is employed, as under the present plan for the settlement of American railway disputes, for the much more difficult problem of the terms of a new agreement. The methods of choosing arbitrators show somewhat similar variations. They may be public men—judges, lawyers, clergymen, professors—either chosen for particular controversies or named as permanent arbitrators in the agreement. They may be officials appointed for such purposes by the government, as under the British Industrial Courts Act. In extreme cases, such as that of the Chicago clothing trade, they may be men devoting their full time to service as "judges of common pleas" within the industry. A recent variant of voluntary arbitration has arisen in the provisions introduced in a number of non-union plans of employee representation for the reference of disputed points to outside authorities. The attempt is to answer the objection that the decisions of "company unions" rest ultimately on the balance of power between a powerful corporation and an unsupported group of workers; but so far there is little evidence that these provisions have been used in practise. The older methods of voluntary arbitration, however, represent an admittedly valuable contribution to the technique of collective relationships. Their most obvious shortcomings lie in the fact that they rest entirely upon consent—consent to arbitrate and consent to abide by the decisions—and that they are quite unlikely to cover either the whole of industry or its most embittered sections.

Voluntary arbitration arises within industry. Compulsory arbitration arises by pressure from outside, when voluntary methods fail or when there is other reason for public dissatisfaction.

When workers and employers fail to agree, the "general public" suffers, and this "party of the third part" may intervene to protect its own interest in industrial peace. Or, on the other hand, sympathetic observers may wish the government to intervene in favor of wages and conditions better than unorganized workers are likely to secure by their own efforts. This latter motive has often led to minimum wage and trades boards legislation, whose working sometimes approximates that of arbitration proper; and it played a large part in the agitation for compulsory arbitration, at least in Australia and New Zealand. Yet there can be no doubt that the demand for industrial peace has been the chief driving force in the movement. Compulsory arbitration is an expedient that is not likely to be seriously urged until unionism is strong enough to threaten interruptions of the production of necessary services. It has, however, not only been urged but tried, as either a temporary or permanent measure, in a number of countries. In the nation of its first adoption, New Zealand, the system has been in operation since 1894. South Australia also passed a law in the same year, but the serious use of arbitration in Australia did not begin until the first years of the present century. Now, however, four of the six states have complete arbitration systems; the two others have wages boards that with the increasing unionization of the workers tend more and more to approach arbitration in practice; and the most famous of all arbitration tribunals, the Commonwealth Court of Conciliation and Arbitration (established 1904), has become the chief agency of wage determination under a steadily broadening definition of "inter-state" disputes. In these two countries the conditions under which the overwhelming majority of wage earners work are set by these bodies; and, in spite of constant criticism on points of detail and occasional sectional attempts to secure their abolition, as for example by New Zealand workers in 1911 and New Zealand farmers in 1928, the broad principles of arbitration are quite generally accepted.

Before the war these experiments stood almost alone. Canada, to be sure, has had its Industrial Disputes Act in force since 1907, and an adverse legal decision in 1924 has limited rather than ended its operation. Yet this law, which was later imitated in Colorado and South Africa, provides for compulsory investigation rather than arbitration proper. Boards are to issue "recommendations" rather than awards,

and the parties are at liberty to reject them. Strikes are illegal only during the investigation, and even this modicum of compulsion has in practice been used much less than the conciliatory provisions of the act. During the war, on the other hand, many nations turned to compulsory arbitration. The emergency intensified the demand for uninterrupted production and was felt to justify and make possible the use of unprecedented compulsion. As a result a large number of temporary tribunals were established, among them the American National War Labor Board and the British Committee on Production. In most cases these bodies were disbanded or lost their compulsory powers shortly after the Armistice, but perhaps an effect of the widespread familiarity with the method has been seen in the number of post-war experiments. In 1920 the state of Kansas created an industrial court with extensive powers over employers and workers in industries of public importance, but its functioning was ended by a series of decisions by the United States Supreme Court (1922, 1924) declaring essential features of the act unconstitutional. In European countries, however, more extensive use has been made of the principle. Norway from 1916 to 1923 employed compulsory arbitration in disputes which the government considered dangerous to the public interest; since that time compulsion has been employed only in the so-called "justiciable" cases of the interpretation of existing agreements. Germany began similar experiments at about the same time, and has retained the principle of compulsion for both types of controversies, though the emphasis is placed on the encouragement of voluntary agreements, and the power to make new and binding awards is severely limited and rarely used. Soviet Russia has naturally emphasized the part of the state in wage regulation and in some cases by forms approximating arbitration in the western countries. At the other end of the political scale, moreover, Fascist Italy has shown itself one of the latest and perhaps the most thoroughgoing of converts to the principle by a 1926 law, which, according to its advocates, "forbids the auto-defense of classes" and provides the alternative of a "complete and organic" system of industrial law.

The tribunals established under these diverse laws are often courts presided over by judges drawn from the regular judiciary or with similar qualifications and privileges. They are sometimes assisted, however, by assessors represent-

ing employers and employees respectively; and procedures are frequently simplified and rules of evidence relaxed to fit the somewhat inchoate matters of controversy. In form, then, compulsory arbitration is at least a semi-judicial process. Is it judicial also in the sense of proceeding to its judgments on the basis of precedent and established principle? The claim is made for the more regular forms of voluntary arbitration, and a fortiori for the compulsory type, that they are creating "a common law for industry" and taking over "a new province for law and order." Certainly it is true that argument frequently takes the form of reference to previous decisions, and that particular boards or courts have built up something like common bodies of practise covering a wide range of subjects. Recognized rights and procedures grow up around such matters as discipline and discharge, and a number of "principles" of wage settlement have been enunciated by thoughtful arbitrators or by students interpreting their decisions. Certain of these are admittedly useful but admittedly partial. Wage adjustment with relation to changes in the cost of living of course offers no complete solution, since no one would accept the principle of the permanent stabilization of real wages at the status quo; yet its use, as in the automatic variation of wage rates under Commonwealth awards in accordance with quarterly fluctuations in an index of living costs, may be of real value in eliminating the many disputes that arise simply out of price movements. Similarly the doctrine of standardization, or the equalization of pay for similar work within or between industries, throws no light on the question of how high the general level should be.

A far more ambitious principle is that of the living wage. Wages must be enough to live on: they must make possible the satisfaction of "the normal needs of the average employee regarded as a human being living in a civilized community." A "basic wage" so established must be "sacrosanct" whatever the difficulties of industry. This doctrine has had great influence upon arbitral decisions. Attempts to define how much is "enough" have led to elaborate budgetary studies, and in two of the Australian states special bodies have been established with "the declaration of the living wage" as their principal function. But enough for how many? Living wages for men have commonly been calculated on the "family-of-five" basis, but critics have pointed out that this means paying bachelors and men with small families for "phantom"

dependents and at the same time leaving unsupported many "flesh-and-blood" children in larger families. It is therefore not surprising that the first two governments to adopt general plans of family endowment have been those of New Zealand and New South Wales, whose courts have long attempted to apply the living wage doctrine. This principle, moreover, offers no guidance for the payment of the workers above the basic wage; and for them the courts rely largely on customary differentials for skill, training, etc. But if the living wage is thought of as setting a lower limit for wage determination, certainly an upper limit is set by industry's "capacity to pay." In one form or another, perhaps only tacitly in basic wage cases but explicitly in all others, this criterion has appeared in all arguments. Yet on the questions of how this capacity is to be measured, whether by the rough test of unemployment after the fact, or by an elaborate index of national productivity, past and prospective, as suggested by a Queensland economic commission, or by some other means, and as to how far particular businesses or industries may be sacrificed without loss to production as a whole, both arbitrators and theorists are very far indeed from agreement. These doctrines, then, are useful generalizations but hardly a body of established principle. Arbitration is still largely legislation and compromise. The choice among rival and conflicting doctrines leaves ample room not only for the "equity and good conscience" which the Commonwealth act commends to its judges but also for expediency and good policy.

In enforcement, also, compulsory arbitration falls somewhat short of the full force and character of law. It is true that its awards are supposed to be binding; and although in certain jurisdictions "legal strikes" may take place under specified conditions, it is typically of the essence of the system that strikes and lockouts are prohibited. Moreover, violations have been punishable by substantial fines upon both individuals and organizations, and in Kansas and elsewhere even by imprisonment, as well as by certain penalties, oftentimes more effective, that consist of depriving the offending union of some of its privileges under the system. Yet the enforcement of these provisions, as against the workers and their organizations, has rarely been complete. Prosecutions are far less frequent than flagrant violations. It is hardly possible to put the entire body of striking workers in jail, and the imprisonment of their leaders is often felt to be

an undesirable way of making martyrs. Even fines, moreover, are frequently remitted for the sake of future good will. It is this laxity in the earlier systems which the authors of the Italian law were most anxious to avoid, yet it has often been defended as essential to the conciliation which is a vital part of most arbitration systems. "The extent to which compulsion has actually been applied has been insignificant in comparison with the degree of settlement through voluntary processes." Agreements reached directly between the parties, sometimes under the tactful encouragement of the judge, frequently have the force of law; and elaborate awards handed down by the courts are often, save for one or two contentious clauses, entirely the work of the contestants. Rigor of enforcement has often been deliberately sacrificed to the encouragement of this spirit of conciliation.

What, then, have been the results of these experiments on the border line between law and persuasion? Common effects could hardly be expected of such diverse methods, nor is there a consensus of opinion among students in the field. Yet certain suggestions, largely negative, may be ventured. The most obvious is that the system has nowhere brought about complete industrial peace. Even New Zealand is no longer "the land without strikes," though it still appears to be the least strike ridden of modern nations. Australia has many stoppages, although few outside the three turbulent groups of miners, dockers and seamen. It may be significant that Australian workmen strike somewhat more often than those of non-arbitration but largely non-union America, but that Australia loses far less time per worker than non-arbitration but largely union Great Britain. The two arbitration countries, moreover, have had the fewest strikes, in proportion to union membership, in the world. Yet this statement involves some circularity, since arbitration typically encourages the growth of unionism. Its technique rests on the representation of workers by their organizations. In practise it protects and stimulates union membership among the less skilled and less courageous workers. At the same time it involves some degree of public control over the unions—in the Italian case a very stringent one—and there can be no question that its tendency has been to turn them from "militant" to "litigious" and perhaps to political organizations. But what has it done to the wages and working conditions which unions attempt to improve? There is no evidence that it has

greatly affected their general level, and trends of wages have been much alike in arbitration and non-arbitration countries. Very likely it has somewhat stabilized wage rates, acting as a brake in times of both rising and falling prices. On the whole it appears to have had a more powerful influence in altering the distribution of income within the working class than between classes. Its most marked effect, both in war time cases and in the longer experience of Australia and New Zealand, seems to have been to reduce the differences between the different grades of labor through its greater emphasis upon the living wage than upon the importance of differentials. As a consequence the rates of pay for skilled and unskilled labor run remarkably close together in the older arbitration countries, with great advantages in the lessening of primary poverty but with danger to the provision of skilled labor. For this last and for other reasons critics charge that the system impedes the proper distribution of the working force between occupations and lessens the incentives to efficiency. Moreover there are many complaints that its lengthy awards fetter industry with innumerable harassing restrictions and that its very structure accentuates the dichotomy of employers and employees. Yet it is by no means clear that either of these objections would apply more forcibly to arbitration than to the strong unregulated unionism which would in many countries seem its most probable alternative.

Current discussion, indeed, appears to recognize that both the merits and defects of compulsory arbitration have in the past been greatly overstated. Conservative critics are now far more likely to attack the system for "rigidity" than for "confiscation," and its radical opponents more often oppose it because of its effect on the morale of the labor movement than because they believe that it robs the workers of much they could otherwise win for themselves today. Similarly very few of its advocates would claim that arbitration can abolish either poverty or industrial conflict, but many would agree that it contributes a useful technique of industrial adjustment.

ARBITRATION, INTERNATIONAL. Arbitration marks an advanced stage in social organization. The settlement of private disputes by that method rather than by force is essential to any organized society. In private affairs the arbitral process is exemplified in early stages of Greek and Roman law in the obligatory resort to private arbitrators and later to established courts. In the public field arbitration was employed from time to time by the Greek city-states, and it played a considerable part throughout the Middle Ages in the solution of interstate disputes. It is not surprising, therefore, that with the growth of the modern state and with the increasing complexity of international relations the resort to arbitration has within certain limits become institutionalized.

International arbitration was defined by the Hague Convention of 1907 as "the settlement of disputes between states by judges of their own choice and on the basis of respect for law." This definition seems too narrow, for arbitration includes every submission of a dispute to final decision by an impartial judge or court. The method of appointing the arbitrators or judges, whether ad hoc by the parties or by election by some independent body, and whether these judges hold temporary or permanent tenure, is less important than the actual judicial process which determines the issue. Its judicial character is the distinguishing mark of arbitration—a factor which has been deemed to limit the scope of arbitration to only certain types of disputes.

The fact that arbitration before the establishment of the Permanent Court of International Justice in 1920 usually involved the selection of judges by the parties has led to the belief that

decision by a fixed tribunal such as the Permanent Court of International Justice constitutes a different process, which has been called "judicial settlement," and that arbitration is not judicial settlement. This is an error. No distinction should be made between arbitration and judicial settlement—for a difference in the method of obtaining judges implies no differentiation in the process of submission and determination. Both may be said to constitute arbitration and both are judicial.

Its judicial character and the finality of the award rendered differentiate arbitration from such diplomatic measures as the offer of mediation and good offices and from such processes as conciliation, inquiry undertaken by international commissions for the investigation of disputed facts, the procedure of making recommendations or the reconciliation of differences without binding finality. The political conclusions of such a body as the Council of the League of Nations, reached not on a basis of law without formal hearing but by independent consideration on a basis of political expediency, must also be distinguished from arbitration.

The Jay Treaty between the United States and Great Britain (1794) marks the beginning of the modern period of international arbitration. Under that treaty three important arbitrations were held. The nineteenth century is replete with arbitrations, involving mainly boundary disputes and pecuniary claims arising out of injuries to aliens. Among the most notable arbitration cases have been those between the United States and Great Britain, including the *Alabama* Arbitration, the Venezuela-Guiana Boundary, the San Juan Water Boundary, the Alaska Boundary Arbitrations and later the Bering Sea Arbitration. Moore's collection of international arbitrations is a repository of the history and awards of the principal arbitrations of the nineteenth century.

The movement for institutionalized arbitration may be said to have begun with the Hague Conference of 1899, from which issued the Hague Convention for the Pacific Settlement of International Disputes (amended in 1907). That convention provided not only for arbitration among the signatory powers of such disputes as they voluntarily agreed to submit, without the exception of any class of cases, but also provided for mediation and international commissions of inquiry. It established the Permanent Court of Arbitration, to be selected by the parties ad hoc from a panel of

some 120 judges nominated by the various countries. To that tribunal, which still exists, some twenty important cases have come. A special agreement (*compromis*) is required in each case, defining the subject matter of the dispute and the powers of the arbitrators. The effort to make arbitration obligatory, a proposal which was voted down at the Hague Conference, has nevertheless been renewed in various forms. The Franco-British Treaty of 1903 was the model for the obligatory arbitration treaties which it was hoped would be adopted, although the obligation was very slight. By this treaty the parties agreed to submit "differences which may arise of a legal nature or relating to the interpretation of treaties . . . provided, nevertheless, that they do not affect the vital interests, the independence, or the honor of the two contracting states and do not concern the interests of third parties."

The United States took an active part in sponsoring the movement for obligatory arbitration in a series of treaties beginning with the Root treaties of 1908. These too, however, excepted disputes involving "vital interests," "independence" and "national honor." The commitment in fact was far behind the actual practise of the United States and Great Britain, for those countries had submitted to arbitration important political questions such as the *Alabama* and *Venezuela* cases, in the former of which Great Britain had first contended that it affected her "honor" and in the latter that it was "political." However, the United States, in an effort to meet the wishes of persons vaguely desirous of promoting peace, signed similar treaties with Great Britain and six other countries. The Senate amended the treaties so as to require its approval for any special agreement to submit specific questions. President Roosevelt first declined to present the treaties to foreign countries in their altered form; but in 1908, when Elihu Root became secretary of state, they were submitted and ratified. The result is that it is now more difficult for the United States to arbitrate a case than it was in 1794, for special treaties are now usually required as a preliminary to arbitration, whereas formerly an executive agreement sufficed. In the Taft-Knox treaties of 1911 with France and Great Britain respectively, provision was made for the submission of "justiciable" controversies and for a joint commission to pass on the question of justiciability in each case. Justiciability is an alternative term for questions of a

"legal nature." The Senate struck out the provision for the joint commission and made numerous reservations concerning so-called "domestic questions," such as the admission of aliens, debts owed by any state, and the Monroe Doctrine. President Taft thereupon abandoned the treaties. In 1913 the so-called Bryan treaties were negotiated with various powers, providing for the submission of all disputes to an international commission for investigation and report. They were known as "cooling-off" treaties, for pending the report war was not to be declared or hostilities begun. Additional treaties of this type have been concluded in recent years, and there are now some thirty treaties in force between the United States and other powers. They have never been actually applied, and as they are practically limited to the determination of disputed questions of fact, they are, contrary to the views of their author, of very limited utility.

After 1919 the United States concluded two treaties on the Root model of 1908 with Sweden and Liberia. The Bryan treaties still remain in force, and in 1928 Secretary of State Kellogg negotiated new arbitration treaties designed to take the place of the Root treaties. The treaty with France, already ratified, has been the model. It provides for the submission of justiciable disputes to arbitration but excepts any dispute which "(a) is within the domestic jurisdiction of either of the High Contracting Parties, (b) involves the interests of third parties, (c) depends upon or involves the maintenance of the traditional attitude of the United States concerning American questions, commonly described as the Monroe Doctrine, (d) depends upon or involves the observance of the obligations of France in accordance with the Covenant of the League of Nations."

The old exceptions of "vital interest, independence, or honor" are thus replaced by new ones believed to be narrower and more precise in scope. The defect of treaties providing for arbitration of legal questions yet excepting from the obligation broad types of issues perhaps not legal in character at all—the existence of the exception to be determined by either of the parties—is that actually they constitute no agreements to submit anything, or at best, agreements to submit everything but that which is important. It is far better for the institution of arbitration to make a positive committal to submit given specific questions without exception.

The effort to make arbitration obligatory was accompanied by an attempt to establish a court with a fixed personnel. The so-called "Court of Arbitral Justice," projected at the Second Hague Conference, failed of establishment because of inability to agree on the selection of a limited number of judges from many states; but that obstacle was overcome in 1920 by the foundation, through a Commission of Jurists acting at the request of the Council of the League of Nations, of the Permanent Court of International Justice. A provision for obligatory arbitration, when recommended by the Committee of Jurists, was modified by the Council of the League on the ground that it involved a departure from the Covenant. The Council provided, instead, that states could *elect* to make arbitration between them obligatory, unconditionally or on condition of reciprocity or for a specified time. Some thirty-five states have signed the so-called "optional" clause (Article 36 of the Statute of the Court), and of these some twenty have ratified. Several of the Great Powers have signed, and Germany has ratified, the clause. Under that clause the signatories agree to permit themselves to be arraigned unilaterally upon the demand of another signatory on any question involving: the interpretation of a treaty; any question of international law; the existence of any fact which, if established, would constitute a breach of an international obligation; or the nature and extent of the reparation to be made for the breach of an international obligation. These are the topics mentioned in Article 13 of the Covenant of the League as "generally suitable for submission to arbitration or judicial settlement." No special agreement is required, and the court determines whether the issue is of a type included in the article. A number of bipartite treaties of obligatory arbitration have been concluded independently. The peace treaties provide that certain types of cases shall automatically go to the Permanent Court; and the court has been given obligatory jurisdiction over certain questions involving aerial navigation, the protection of minorities, the African liquor traffic, communication, the arms traffic convention and the Barcelona waterways convention. Practically none of these provisions has yet been tested, although Belgium has invoked the court's compulsory jurisdiction in its dispute with China arising out of China's denunciation of the treaty of 1865.

Attempts at introducing the principle of arbi-

tration since the war have been made whenever possible in all countries. The Protocol for the Pacific Settlement of International Disputes, drafted at Geneva in 1924, which set up an elaborate scheme for outlawing all aggressive war, with an obligation to submit practically all disputes to obligatory arbitration, may be regarded as dead. On the other hand the European signatories of the Locarno treaties of 1925 have by those treaties agreed to submit to an arbitral tribunal or to the Permanent Court of International Justice any legal question, particularly of the type mentioned in Article 13 of the Covenant of the League, namely: the interpretation of a treaty; a question of international law; a fact which would constitute a breach of an international obligation; and the nature and extent of reparation for such breach. In 1928, with the intention of supplementing the Locarno treaties, the Committee on Arbitration and Security of the League of Nations submitted to the Assembly of the League three "model" arbitration and conciliation conventions which attempt to differentiate between "legal" and "non-legal" disputes, the former to be submitted to arbitration, the latter to conciliation; but thus far no state has accepted the model conventions.

The Latin American states have been especially devoted adherents to the principle and practise of arbitration. Their similarity of origin, culture, legal tradition and political experience facilitated the resort to arbitration. Boundary disputes among them have been frequent, but with minor exceptions they have been settled by arbitration. During the nineteenth century these countries have been parties to eighty-four arbitrations.

The First Pan-American Conference in 1889 declared arbitration to be a principle of "American International Law." The second conference in 1901 and the third conference in 1906 similarly expressed adherence to arbitration in principle, but inability to agree on the scope of arbitration arising from the conflict of interest between the United States and Latin American countries prevented the ratification of the actual treaties proposed. The later conferences have been attended by greater success. At the fourth conference in 1910 a General Claims Convention was adopted for the submission to the Permanent Court of Arbitration at The Hague of all claims for pecuniary losses and was ratified by the United States and by eleven Latin American countries. At the Fifth Pan-American Confer-

ence in 1923 the Gondra Treaty was adopted providing for the submission of all except constitutional disputes to commissions of inquiry.

At the sixth conference at Havana, 1928, it was agreed to call a special conference in Washington in December, 1928, for the purpose of adopting a multilateral treaty for the solution of differences of a "juridical character." By the treaty, adopted in January, 1929, the twenty republics agreed to submit to arbitration "differences" arising "by virtue of a claim of right . . . which are juridical in their nature by reason of being susceptible of decision by application of the principles of law." It then specifies these questions as the four contained in Article 13 of the Covenant of the League and Article 36 of the Statute of the Permanent Court, namely: the interpretation of a treaty; a question of international law; a fact which would constitute a breach of an international obligation; and the nature and extent of reparation for such breach. The treaty excepts questions which are within the "domestic jurisdiction" of a state and which international law does not control, as well as those which affect the interest or refer to the action of third states—an exception deemed broad enough to include the Monroe Doctrine, which was not mentioned. Seven states—Brazil, Cuba, Haiti, Nicaragua, Panama, Peru and the United States—signed the Pan-American Treaty of Arbitration without reservations. The other thirteen states made reservations of a somewhat limited character, for the most part simply declaratory of international law.

In 1907 the Central American republics had set up a permanent arbitral tribunal—the Central American Court. After deciding several cases the court was abandoned in 1917 as a result of the rejection by Nicaragua of the court's award regarding the Bryan-Chamorro Treaty. The Central American Conference of 1923 established a new Central American Court, which is to draw its judges ad hoc from a panel of judges appointed by the several states, and which excludes questions affecting sovereignty, independence, honor and vital interests from its jurisdiction.

In the progress of international arbitration some fundamental principles of procedure have been developed which have greatly facilitated the settlement of disputes. Under the Hague Convention of 1907 the two parties must agree upon a *compromis*, which defines the issue in dispute, the mode of appointing arbitrators, the scope of their powers, the language to be em-

ployed, the place of meeting and in general the conditions upon which the parties submit the case. Within limits the tribunal may be called upon by the parties to settle details upon which they cannot agree. The duties of arbitrator may be conferred upon one or several persons. If the arbitrator is the head of a state, he is to settle the procedure. Each party may appoint one of its own nationals, in which event there must be an umpire. The parties may appoint agents and counsel to present their cases to the court. The proceedings are in writing, with the submission of cases, counter-cases and, if necessary, of replies, to which exhibits may be attached. Oral argument may supplement the written submission. The tribunal may make rules of procedure for the conduct of the case, deciding the form, order and time in which each party must conduct and conclude its arguments, and may arrange formalities for dealing with questions of evidence. In general the tribunal has broad discretionary powers to determine the procedure for the submission of the case. It may determine its own competence in interpreting the *compromis* and the evidence and in applying the principles of law. The decision is made by majority and is final and without appeal. Any dispute as to the interpretation and execution of the award is to be submitted to the tribunal. The Hague Convention also makes provision for summary procedure, which differs from the regular procedure only in the fact that each party in dispute appoints an arbitrator, and the two thus selected choose an umpire. If they do not agree, each arbitrator nominates two non-national candidates from the general panel of the court, and from these the umpire is determined by lot.

The procedure before the Permanent Court of International Justice, except as to Article 36, providing for obligatory arbitration, does not differ materially except that the parties have nothing to do with the selection of judges; they have only the privilege of nominating a national judge on the court ad hoc, if there is not already a national judge on the court. Proceedings are initiated by the filing of a written "application" addressed to the registrar of the court indicating the subject of the dispute and the names of the contesting parties. The registrar communicates the application to all parties concerned and to the secretary general of the League of Nations. Procedure before the court is both written and oral, as in the case of the Permanent Court of Arbitration. The hearing in

court is public unless the court, at the request of one of the parties, decides otherwise. The court determines the rules for the conduct of the case and makes all arrangements connected with the taking of evidence. The court may call upon the agents to produce documents and furnish explanations before the hearing begins and witnesses may be called. The court may entrust to any individual, commission or bureau it may select the task of conducting an inquiry or giving an expert opinion. Decisions by default are possible, provided the court is satisfied that it has jurisdiction and that the claim is supported by substantial evidence and is well founded in fact and law. The judgment is final and without appeal and must express the reasons for the conclusion reached. At the request of either party the court must construe its judgment, if uncertain. A special chamber of five judges, aided by four technical assessors, may deal with labor, transit and communication cases.

The plan of the Pan-American Treaty of Arbitration, 1929, limits the opportunity for disagreement on the terms of a *compromis*. Such special agreement concerns mere details. Definite provision is made for the setting up of a tribunal if the parties cannot agree, although the parties may select any arbitrator or tribunal they desire. If the parties do not agree upon a tribunal, each party must nominate two arbitrators, of whom one only may be its national. These four in turn select a fifth arbitrator, who is to be president of the court. If the four arbitrators do not agree, an alternative provision is made for the designation by each party of a non-American member of the Permanent Court of Arbitration; and the two persons so designated select the fifth arbitrator. Instead of leaving the final choice of the fifth arbitrator, who may be all important, to the drawing of lots, the choice is made by designated jurists—a provision designed to secure the selection of an impartial and well qualified person. The parties are required to formulate a *compromis* defining the subject in issue, the seat of the court, the rules of procedure and other conditions on which they may agree. If the parties do not reach an accord on these questions within three months from the date of the establishment of the court, the agreement must be formulated by the court itself. The award is final and without appeal.

This machinery makes it more possible to extend the scope of international arbitration. It
